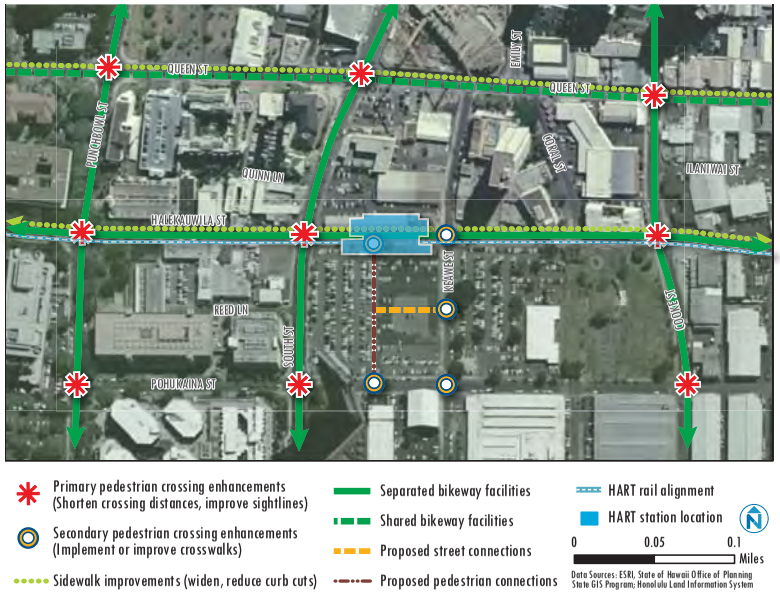
Located on Halekauwila Street between South and Keawe Streets, Civic Center is the primary station for the district's many local, state and federal employees and visitors. Civic anchors and institutions include the Honolulu City & County Buildings, State Capitol District, Queen's Medical Center, Social Security Administration, and US Customs & Immigration. The station's site at the periphery of the district, however, will require passengers to walk or bike for the last leg of their trips. The recommended strategies and actions below focus on key priorities for enhancing multimodal access to these major destinations.

TRIMET APPROACH TO CALCULATING STATION BIKE PARKING

Portland is a national leader in bicycle accommodation and its public transit provider, TriMet, sees providing safe, secure access to transit for cyclists as a cornerstone of regional mobility. As part of its latest light rail project, the Portland to Milwaukee line, it developed a model for assessing bicycle access to stations based on each station's land use context, location, and availability of bicycle facilities. The model is used to determine how much bicycle parking to construct at each station. The model uses projected station ridership, transit frequency, urban context (center city, neighborhood, suburban, etc.) and bikeway network inventory data to determine optimal and minimum number of bicycle parking stalls. A similar approach was used to calculate bike parking requirements for the two stations in the KCDD.



A card-access bicycle parking facility at a suburban TriMet light rail station.

Long-term bike parking at a SkyTrain Station in Vancouver, BC.
Image from Nelson\Nygaard

Figure 7-9 Civic Center Station Access and Circulation

Action SA8.1 Establish Punchbowl Street as the primary pedestrian route between the station and local, state and federal campuses.

Punchbowl Street will be a major pedestrian conduit for transit riders traveling to the City & County of Honolulu buildings, the State Capitol District and federal facilities. It also provides a direct path to the busy bus transit stop at Punchbowl and King. To take advantage of its existing pedestrian amenities (zebra crossings, pedestrian signals, street trees), it should be promoted as the primary route through signage and wayfinding. Signage should provide clear direction to regular commuters as well as visitors and residents that access the government facilities on a less frequent basis.

Wide sidewalks accommodate high pedestrian volumes near a SkyTrain station in Metro Vancouver.
Image from Nelson\Nygaard

All three east-west oriented streets in the vicinity of the station – Queen, Halekauwila, and Pohukaina Streets – should all be treated as major pedestrian access ways to Punchbowl.

Action SA8.2 Enhance pedestrian experience along Halekauwila, Queen, and Pohukaina Streets.

While it will be critical to provide a quality pedestrian environment on Halekauwila in the vicinity of the station, pedestrians are not anticipated to travel long distances on this street. The introduction of an elevated guideway in this relatively narrow right-of-way will make the street relatively less appealing for walking. Features such as vibrant ground floor retail and street-front cafes, which contribute to a vital walking environment, are less likely to locate immediately adjacent to the guideway, making parallel streets such as Queen and Pohukaina more attractive for pedestrians. Important steps for improving the pedestrian environment on these streets will include:

- Integrate pedestrian scaled lighting into the elevated guideway structures or in the sidewalk furniture zone. Reduce the number of curb cuts along Halekauwila, Queen, and Pohukaina to ensure universal accessibility and limit the number of pedestrian-vehicle conflicts.
- Implement pedestrian crossings at the intersection of Halekauwila and Keawe.
- Construct mid-block crossings regularly along Halekauwila.
- Enhance pedestrian crossings on Queen and Pohukaina where they intersect Punchbowl, South, and Cooke. Improvements may include tightening corner radii, reducing crosswalk distances with curb extensions and pedestrian refuges, and addressing other sightline issues.

Action SA8.3 Improve pedestrian crossings in the Civic Center area by improving sightlines and shortening crossing distances.

Although pedestrian crossings in the Civic Center station area are generally marked, signalized or stop sign protected, many of them are angled, thereby impairing sightlines, and entailing longer crossing distances. This is especially true on the mauka side of the station along Queen and King Streets. Sightlines at these intersections could be improved by restriping crosswalks perpendicular to sidewalks. Curb extensions, or bulb-outs, should be implemented to reduce crossing distances.

Action SA8.4 Provide interim pedestrian walkways and preserve long-term connections through the surface parking block on the makai side of Halekauwila Street.

Interim pedestrian routes through the surface parking lot would provide direct access from the station to high-density development. As this lot is developed, a mauka-makai running center block pedestrian pathway should be considered (such a facility is included in the Kamehameha Schools Master Plan). Running parallel to the station, an extension of Reed Lane could be planned for a future connection to the Mother Waldron Playground.

Action SA8.5 Integrate a bike share station into the Civic Center Station design, and provide space for expansion.

Given the added distance from the station to many of the major destinations in the area, Civic Center is an ideal candidate for a bike sharing station. Likewise, the employment concentrations at those destinations provide the critical mass of potential users to warrant bike stations of their own.

The station area should be designed to accommodate a 20 bike station with capacity to expand to 56 bikes by 2035. The approximate spatial requirements for the initial station and a 2035 build-out station are provided in the table below:

Figure 7-10 Spatial Needs for Bike Share at Civic Center HART Station *(Opening Year and 2035)*

Year	Docks	Width	Station Depth	Access Depth	Total Depth
Opening	20	52' - 54'	6' - 8'	4	10' - 12'
2035	56	112'- 114'	6' - 8'	4	10' - 12'

Action SA8.6 Increase the supply of short- and long-term station bicycle parking at Civic Center Station.

Bike sharing programs help meet "last mile" connection needs at transit stations.
Image from Nelson\Nygaard

Initial estimates from the HART station access plans are to provide 20 bicycle parking spaces for opening day service, increasing to 110 total in 2030. Based on the access demand estimates, an additional 10 spaces are recommended for opening day service. In 2030, that demand is expected to grow to 130 spaces with the implementation and build-out of planned TOD densities. Additionally, station design should anticipate the need for future growth in station area bike parking. A long-term bicycle storage facility that accommodates 30 bicycles is recommended. This facility should be located as close as possible to or, if possible, inside the fare gate.

Since this station is expected to be the destination end of most than 80% of home-based trips to and from the station, bike-share will be a critical strategy to complete last mile connections in the KCDD and adjacent neighborhoods.

Action SA8.7 Promote South Street as a major bicycle route accessing the station and institutional uses.

The Civic Center station is located on the periphery of many large government employers. While in the future it will be the center of an active mixed-use area, in the short- to mid-term attention must be paid to the last mile connections for potential transit riders. For instance, the station is over

½-mile to the State Capitol and the Queen's Medical Center. Although still within reasonable walking distances, these destinations are ideally suited for short urban bicycle trips. To this end, South Street's existing right-of-way width and capacity affords opportunities for innovative separated bicycle facilities. Its one-way operations, however, make traditional bike lanes on opposite sides of the street problematic. Rather than having to provide facilities on parallel streets, cities have addressed this condition by implementing contraflow bike lanes on the same side of the street. A pilot project on 15th Street in Washington, DC yielded a 40% increase in bicycle traffic and a 7 mph reduction in vehicle speeds within one year.

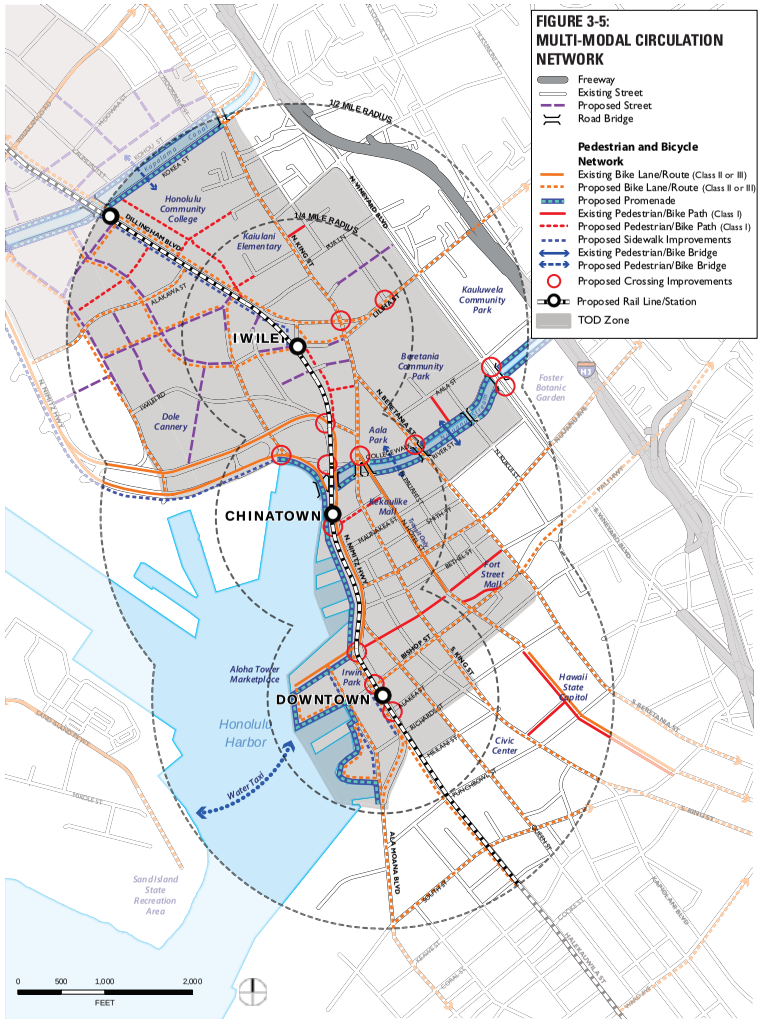
Two-way cycle track on 15th Street in Washington, DC.
Image from Green Lane Project

An alternative to two-way cycle track on South Street is to couple it with Punchbowl Street as parallel one-way facilities going in their respective directions.

Action SA8.8 Provide separated bicycle facilities along Cooke Street.

Separated bike lanes on Cooke Street would provide direct access to the University of Hawai`i School of Medicine and the Kaka`ako Waterfront Park.

Strategy SA9 Implement actions specific to Downtown Station (related to redevelopment of Aloha Tower portion of the District)



The Downtown HART station sits at the makai edge of the Aloha Tower Marketplace. This area of the KCDD also includes the HECO Powerplant site which is slated for redevelopment. The City/County Kilihi-Downtown Framework Plan calls for the area surrounding this station (including Aloha Tower site) to be developed as intensive mixed use development. The Framework Plan calls for maximum FAR of greater than 7 for this site and surrounding properties .

The City and County has completed a Downtown Neighborhood Transit Oriented Development Plan that provides detail on land use, station integration, and design for the Downtown Station. This plan documents specific transportation existing conditions and proposed access and mobility projects.

Action SA9.1 Implement Connectivity Improvements from the Downtown Framework Plan

The Kilihi-Downtown Framework Plan calls for improved trail access and sidewalk improvements that would improve Ewa Diamond Head connectivity between the Aloha Tower Area and other parts of the KCDD. HCDA should work with the City/County DTS to prioritize and complete these improvements which are illustrated in Figure 7-11 excerpted from the Kalihi-Downtown TOD Framework Plan.

Figure 7-11 Connectivity Improvements for Downtown HART Station Area

Action SA9.2 Create a seamless and inviting pedestrian connection between Downtown and the Aloha Tower area

Introduction of the downtown station represents an opportunity for transformational change at what currently is the greatest pedestrian barrier between Downtown and the Waterfront/Aloha Tower area- the Nimitz Highway. HCDA should work with HART and the City/County to enure the design of this station includes significant placemaking investments and prioritizes mauka – makai pedestrian movements.

The station should have pedestrian entrances on both sides of Nimitz Highway to ensure passengers can ascend to the platform without crossing the Highway. Pedestrian cross-block concept would create a high quality public space and pedestrian crossing opportunity at Nimitz. This could be designed as a pedestrian-scramble intersection allowing all users to cross at the same time anywhere on the block .

The Haleakuwila cycle track concept presented in Chapter 5 provides an opportunity for excellent Diamond Head side bike access to this area. Similar attention should be given to connections from the Ewa direction.

Pedestrian Circulation Across Nimitz:
- Irwin Park extension across Nimitz
- Entire block that will function as a crosswalk
- Provides an area of Nimitz that is at the pedestrian scale
- Allows motor vehicles to only need to stop once for pedestrian crossing

Pedestrian Crossblock

Pedestrian improvements between the Downtown Station and Aloha Tower Special District.

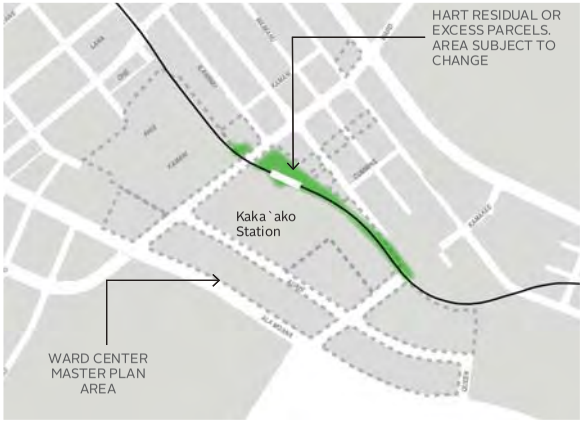
Station Integration Opportunities

This section identifies strategies and opportunities that require coordination and engagement between HCDA and HART. Integration opportunities are established for the three HART stations: Kaka`ako Station, Civic Center Station, and Downtown Station.



Opportunities for Kaka'ako Station Integration

Located on the mauka edge of the Ward Center master planned district, there is great potential for collaborative TOD development at Kaka`ako Station. . The current Ward Center Master Plan already envisions this area as a mixed-use, high-rise neighborhood. The TOD Overlay will provide opportunities to better address street level connectivity with public open space connections to Kaka`ako Station (see also Figure 7-5), district parking options as well as provisions for more intensive uses.

In addition, the immediate station site and alignment include several adjacent residual or excess parcels (shown below) associated with HART construction. These areas may eventually be good candidates to incorporate future retail, public or civic uses.. A single or double story structure adjacent to the station would help to activate the area while allowing room for pedestrian movement and generous gathering places.

It is recommended that if an Iconic tower (a building over 550' in height) is to be located in Auahi Neighborhood at Kaka`ako Station, it should be set back from the station site to ensure that adequate space for pedestrian and vehicular circulation and future local transit service connections. HCDA, HART and the land owners are currently coordinating arrangements necessary for integrated redevelopment. Precedent best practices at similar station locations are discussed in the sidebar on the following page.

Figure 7-12 Kaka`ako Station at Ward Center

BEST PRACTICES IN RETAIL INTEGRATION

Broadway /Commercial Station SkyTrain The Hub - A low scaled retail building is incorporated adjacent to an Elevated rail transit exchange. This provides eyes on the street, and a retail presence to keep people safe, provide a sense of place and wayfinding. This single story structures adjacent to the station to activates the area, and allows for room for pedestrian movement and gathering places.

Westlake Center in Seattle, WA is a good example of elevated retail associated with a public plaza. Westlake center is also a transit hub with connections to light rail, and regional and local bus service below. Major developments are set back from the rail station from one half to one block.

Opportunities for Civic Center Station Integration

There are a variety of opportunities for TOD redevelopment within close proximity to Civic Center station, including sites directly mauka and makai of the station. The HART Station Area Development Potential Report (2011) asserts that Civic Center Station has "perhaps the greatest (redevelopment) potential of any station along the project alignment excluding the West O`ahu stations." Underutilized parcels here surround the station, existing uses include surface parking lots, low-rise warehouses and garages. The 690 Pohukaina catalyst project is located at Keawe and Halekauwila, one block from Civic Center Station, while the parcel directly makai of Civic Center is a part of the Kamehameha Schools master plan and is currently proposed for a high-rise housing project. The following diagram provides an overview vision of TOD potential for the Civic Center station location.

Figure 7-13 Civic Center Station Vision and Opportunities

1 TOD Opportunity Sites mixed-use and residential uses

2 Activate station with uses, maximize glazing and open shopfronts

3 Place bus stops convenient to station, consider integrating shelters into development sites

4 Coordinate with TOD developments for street improvements, crosswalks, lighting and public art

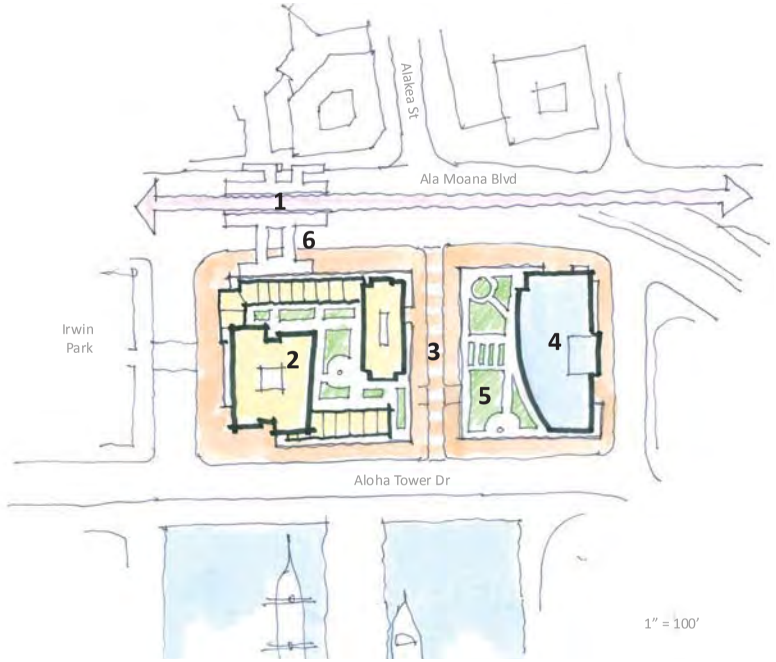
5 Encourage single story retail to activate parking, for example - produce or market stalls

6 Establish bike lanes and local access connections

7 Option for vertical retailing and mezzanine connection to station

8 Step-back development for generous sidewalk areas and public realm enhancements

9 New alley and connections to reduce pedestrian conflicts



10 Pedestrian improvements, crosswalks and accessible ramps Station-related public realm improvements, kiosks or bike-related retail

11 Joint development 690 Pohukaina and affordable housing project

Opportunities for Aloha Tower Special District, HECO Site, and Downtown Station Integration

Downtown Station is within close proximity to the Aloha Tower marketplace, the downtown commercial core, Irwin Park and Honolulu Harbor. It is the primary station serving Honolulu's central business district. The HECO substation parcel adjacent to Downtown Station is particularly well positioned for TOD redevelopment for a range of uses, as it enjoys waterfront views and proximity to downtown. Under the TOD Overlay plan this site would be able to develop using an increase in capacity with more flexibility in off-street parking requirements. This vision is coordinated with the City and County of Honolulu Downtown TOD Plan (2012) that envisions this area as a mixed-use, high intensity district appropriate for high rise buildings. The Plan also recognizes an opportunity for revitalizing the Aloha Tower HECO substation complex into a citywide destination and community-gathering place.

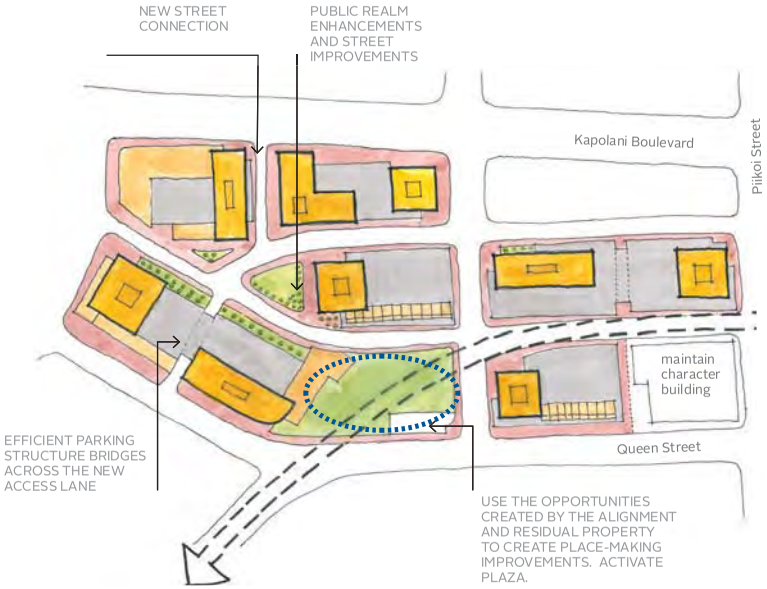
2 Multifamily residential opportunity site

3 Shared street

4 Commercial / office opportunity site

5 Integrated public space

6 High-quality pedestrian plaza and integrated roadway crossing



Opportunities for the Elevated Alignment

Integrating the overhead alignment into a working neighborhood requires special attention to shadow creation, and spaces around columns. Existing uses on Halekauwila St. include light industrial services, shops and a variety of walk-in trade establishments. Unintended impacts of the elevated rail include underutilized land or vacant storefronts adjacent to the guideway. HART is currently collaborating with HCDA to ensure that the design of the elevated alignment will address this areas incremental urbanization. In particular HCDA and HART will coordinate to ensure that the impact on the pedestrian environment is reduced.

In Bangkok, under the transit alignment is a busy, urban place
Image from Google Earth

Figure 7-15 Alignment Design Opportunities

Activating the Alignment

HCDA should prepare for transition, by working with property owners to activate below the guideway where feasible, as well as partnering with HART and the private sector for the provision of active public spaces such as paths, exercise courses, community gardens, lighting and art, shops or storefronts. HCDA and HART will coordinate to

- Reduce impact and number of supportive dual columns that crowd the urban context.
- Locate ancillary buildings such as electrical transformers, maintenance facilities to provide both operational efficiency and better respond to urban context.
- Welcome users by activating ground levels with retail or other commuter uses, such as services or daycare and bike share stations.

Urban Design and TOD Impacts of Elevated Rail

Parcels adjacent to, or within the sphere of influence of the alignment will be impacted in a variety of ways over the course of the project, ranging from land acquisition (and the creation of some residual land parcels adjacent to the Kaka`ako Station site), to construction nuisance, and noise impacts from the overheard train. At the same time these areas will also see significant private sector benefits typical to transit rich areas such as:

- Increased land values, and real estate performance (rents and lease rates)
- Increased retail sales
- Increased access to labor pools
- Increased affordability due to increased access and reduced parking costs by providing transit alternatives
- Renewed vitality as a destination

HCDA and its public sector partners will work to ensure that the benefit of the rail can be broadly shared in the form of improvements to local infrastructures and specific transit-oriented development projects that will locate more investment within proximity of the station. The HART Station Area Development Potential Report (August 2011) conducted an analysis identifying underutilized parcels and opportunities for redevelopment within each station's quarter-mile. This report documented that redevelopment potential is greatest at the three West O`ahu stations followed closely by the Kaka`ako District's Civic Center Station. In order to best meet this potential for redevelopment, the following presents a set of recommended strategies to be conducted during the phases of HART design and construction, with a focus on integrated decision-making.

Strategy SA10 Collaborate with HART in order to integrate station design with TOD sites and catalyze redevelopment.

In order to best meet this potential for redevelopment, HCDA must implement or collaborate to achieve the following actions during the phases of HART design and construction, with a focus on integrated decision-making.

HCDA ACTIVITIES

HART Complete (2019) — Construction phase (2016-2018) — Current phase (2013)

- **Action SA10.1** Work with agency partners to plan transit stations and associated infrastructure that are attractive public destinations, are integrated with the public realm and promote ridership.
- **Action SA10.2** Develop strategies for private-sector engagement with partnerships, demonstration and/or catalyst projects to spur desired uses (see Chapter 3, page 3-19).
- **Action SA10.3** Provide a vision, design and principles for the station design, and support redevelopment with high trip-generating land uses (see Chapter 3, page 3-6).
- **Action SA10.4** Collaborate with jurisdictional and private sector partners to provide market-place comparable, such as the 690 Pohukaina joint-development project. (Chapter 3, pages 3-21).
- **Action SA10.5** Meet with local stakeholders to reinforce the benefits and opportunities of TOD, include financiers, lenders, property owners and developers.
- **Action SA10.6** Partner to provide a vision for residual properties impacted by the rail, including clarifying liability. Consider a method, if necessary to land-bank residual properties resulting from construction areas for future high intensity development so they do not result in long-term underutilization.
- **Action SA10.7** Continue to work towards the evolution of Kaka`ako District, including large and small scale redevelopment, master plans and priority complete streets and access upgrades as defined in this chapter.

Strategy SA11 Establish partnerships with key stakeholders to ensure successful station integration and TOD design.

In urban environments, success will be achieved if transit becomes just one part of the overall public experience of Kaka`ako as a destination. The implementation of this vision will require a partnership among agencies over the course of the project to ensure that land use, transportation and access policies are coordinated for optimal outcomes. Most importantly, HCDA will encourage creativity with neighborhood transformation, by planning for, and encouraging both large-scale redevelopment and incremental adaptive-re use to advance TOD objectives. The following summarizes roles for the public sector (HCDA and City/County), private sector and HART in creating both transit-oriented development and influencing the creation of place at a station site.

Public Partner (HCDA and City/ County)	Private Partner	Transit Agency
Development Regulations /Permits	Development Proposals	Alignment / Station Design
Land Acquisition and Consolidation	Land Assembly	Land Acquisition for System
Environmental Reviews	Architecture and Programming	Planning Partner
Community Facilitator	Entitlements	Construction Facilitator
Land Owner Incentives	Construction	Urban Design Guidelines for Stations and Alignment
Priority Infrastructure Improvements and Public Facilities	Occupancy/ Maintenance/ Selling	

DRAFT

DRAFT

8 PARKING & TRANSPORTATION DEMAND MANAGEMENT

8 PARKING & TRANSPORTATION DEMAND MANAGEMENT

Role of Parking

The pivotal role of parking in all aspects of the life and economy of an urban district is often overlooked. Because provision of parking is very costly, the amount of parking required is often a key determinant of the quality and quantity of new development. The price and availability of parking influences how people choose to travel and whether they will travel to destinations within the district. The amount of space dedicated to parking is a determining factor is the form development takes and to the experience of a pedestrian within the district. Adopting a sensible and well-tailored approach to managing parking may be the single most important thing that HCDA can do to foster a pedestrian-friendly, transit-oriented Kaka`ako community. This section details specific steps that should be taken to manage parking in the KCDD.

Existing Regulations

Off-Street Parking

The Mauka and Makai Plans include parking standards for each land use type, including the quantity of off-street parking and loading spaces that must be provided. A summary of these minimum parking requirements is provided in Figure 8-1.

Figure 8-1 Existing Off-Street Parking Regulations

Land Use	Mauka	Makai
Residential		
Detached dwellings, live-work, and duplexes	2/unit + 1/ 1,000 sq ft of floor area over 2,500 sq ft	Not Applicable
Multi-family dwelling (<600 sq ft)	0.9/ unit	0.9/ unit
Multi-family (600-800 sq ft)	1.25/ unit	1.13/unit
Multi-family dwelling (>800 sq ft)	1.25/ unit	1.35/unit
Group homes, care, convalescent and nursing home	0.9/ 4 patient beds, dwelling units, or lodging units	0.9/ 4 patient beds, dwelling units, or lodging units
Commercial		
Commercial, clinics, administrative and all other uses	1/ 450 sq ft of floor area	1/ 400 sq ft of floor area
Restaurants and bars, and dance-nightclubs	0.9/ 300 sq ft of eating or drinking area + 0.9/ 25 sq ft of dance area + 1/ 450 sq ft of kitchen or accessory area	1/ 300 sq ft of eating or drinking area + 0.9/ 25 sq ft of dance area + 1/ 400 sq ft of kitchen or accessory area
Industrial, media production, printing and publishing and warehousing	One per nine hundred square feet of floor area	Not Applicable
Education and Assembly		
Group assembly/Auditorium	0.9 per three hundred square feet of assembly area or 0.9 per ten fixed seats, whichever is greater	0.9 per three hundred square feet
Religious facilities and theaters	0.9 / 5 fixed seats OR 50 sq ft of general assembly area (whichever is greater)	0.9 / 5 fixed seats OR 50 sq ft of general assembly area (whichever is greater)
Day-care facilities	0.9/ 10 enrolled capacity	1/ 10 enrolled capacity
Educational (elementary and intermediate level)	0.9/ 20 students of design capacity + 1 / 450 sq ft of office floor area	Not Applicable
Educational (high school, vocational, technical university, etc.	0.9/ 10 students of design capacity + one per 450 sq ft of office floor area	1/ 10 students of design capacity + one per 400 sq ft of office floor area
Waterfront Industrial	Not Applicable	1/1,000 sq ft of floor are or 1/ 2 employees, whichever is greater.

Source: KCDD Mauka and Makai Area Plans

Minimum parking requirements like these have emerged as one of the biggest obstacles to many cities' efforts to encourage new residential and commercial development in downtown areas, especially in cities like Honolulu where nearly all parking must be provided in multilevel above ground facilities. With the cost of providing multilevel parking spaces exceeding $50,000 per space, it no longer makes sense to provide more parking than is needed, since the value put into unused parking could be used for a higher quality of development or for additional amenities. Furthermore, the availability of plentiful and unused parking will ultimately undermine efforts to create a walkable transit-oriented community. More specifically, minimum parking requirements have been shown to:

- Create an "oversupply" of parking in most communities in all but the highest periods of parking demand
- Devalue the true "costs" of parking to drivers, thereby creating an incentive to drive, which results in more local congestion and vehicle emissions
- Require tremendous amounts of land, thereby degrading the physical environment and impacting a community's urban form, design, and aesthetics
- Limit the ability to do urban "infill" projects or adaptively reuse historic structures
- Make development projects more expensive and reduce overall profitability

It is very difficult to create a walkable, bikeable environment when more land is dedicated to parking than to buildings. The oversupply of parking resulting from minimum parking requirements can be particularly damaging to uses such as restaurants, which help create a sense of streetlife.

High levels of temporary residency and out-of-state ownership in Honolulu further exacerbate the disparity between supply required by minimum parking standards and actual levels of use at any given time. While KCDD developers report that the market for high-end condos demand some level of guaranteed parking sold with the unit, lower- to moderate-income units may not, particularly if other choices for mobility are available.

On-Street Parking

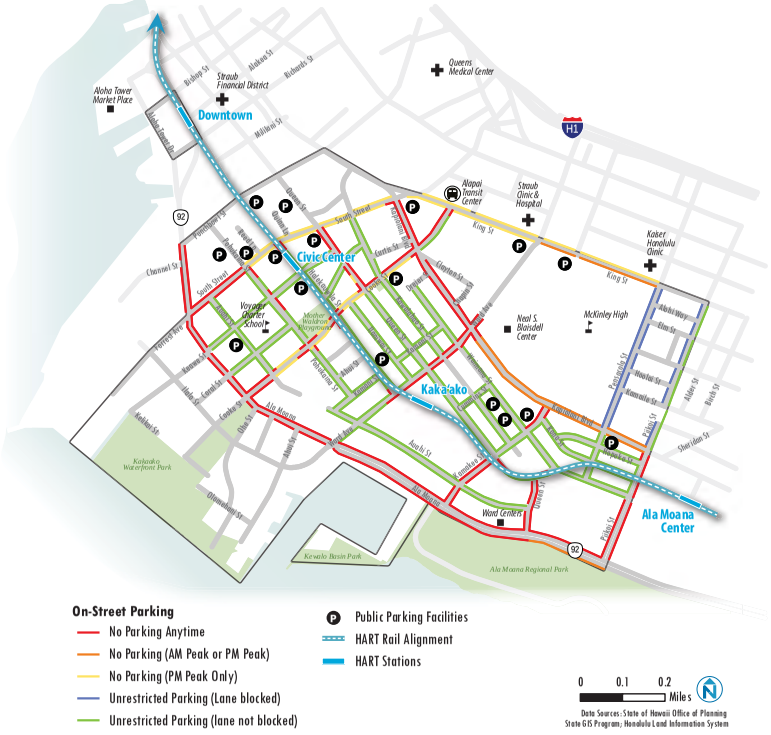

Figure 8-2 illustrates on-street parking in Kaka`ako. Curb parking is regulated as follows:

- On the major regional Boulevard, curb parking is not permitted at any time or at least not during peak travel hours.
- On portions of Cooke, South, and S. King Streets, Parking is not permitted during the PM peak period, while portions of Kapiolani and Ala Moana Boulevards restrict parking during both the AM and PM peak periods.

- On-street parking is free on many blocks in the district: relatively few streets east of Cooke have parking meters. To the west of Cooke, many streets are metered including Pohukaina, Halekauwila, Auahi, Kawaiahao, Cooke, and Queen Streets in the Civic Center neighborhood. Other streets in that same district remain unmetered.
- Where curb parking is permitted, there is a mix of completely unrestricted parking, and parking with 1- or 2-hour time limits.

On weekdays, unrestricted parking typically fills to capacity with long-term parkers early in the day, while time-restricted parking goes largely unused.

Figure 8-2 On-Street Parking Regulations

Source: Kaka`ako Mauka Specific Plan SEIS

Given high levels of employment and relatively few retail or residential uses in Central Kaka`ako, street or alley parking that is not time-limited fills quickly in the morning, while time-limited on street parking remains highly underutilized through much of the day.

Parking with no time limits is full in the early morning.
Image from Nelson\Nygaard

Poorly managed on-street parking can have other negative consequences for the transportation system and the quality of the public realm: When demand for curb parking exceeds supply, drivers end up circling the block searching for an available parking space. This behavior wastes time for drivers and generates unnecessary traffic and emissions: *some studies have shown that as much as 30% of traffic in the busiest downtown areas is the result of circling for parking.* Drivers searching for parking also tend to be more distracted and less attentive to the road, which can increase the collision risk for pedestrians, cyclists, and other drivers.

Time-restricted parking, particularly supply further from the Downtown/Civic Center area, is underutilized.
Image from Nelson\Nygaard

A Market-Based Approach to Parking

Parking is not an end in itself, but rather a means to achieve and support broader community goals and priorities. Rather than focusing on providing an arbitrarily chosen quantity of parking, successful transit-oriented communities actively manage parking to ensure on-street or easily accessible public parking availability for visitors, while right-sizing supply for new development; and allowing the market to determine parking's appropriate price and its value relative to other potential uses for land. Eliminating arbitrary parking minimums does not eliminate new parking supply; rather it allows development to build the precise amount of parking they need to keep their development viable.

Key principles for this approach are as follows:

- **One size does not fit all.** Parking regulations and management strategies should be tailored to the district, and careful measurement of real-world parking supply and demand.
- **Ensure that some parking is always available.** Parking facilities should be managed to achieve 85-90% occupancy, which represents the optimal balance between ease of finding a space and the efficient use of parking resources. This is particularly important for the most visible spaces on the street, and close to garage entrances. If occupancy rises above 90%, it should increase in price, a reduced time limit, or another measure to increase availability. A well managed parking system will almost always have one parking space available on each block face, so that no one is forced to "circle" to find parking near their destination.
- **Share information about parking availability.** Economic success depends not just on the availability of parking, but on the public's perception of availability. Wayfinding should be used to ensure that drivers know where to look for available parking.

- **Share Parking.** Whenever possible, parking should be managed as a shared resource, rather than reserved for customers of a particular business. A city's parking supply is also a public good that needs to be actively managed so that it can meet parking demand during different seasons, different days of the week, or even at different times throughout the day.
- **Manage the entire parking supply as part of a coherent system.** To the extent possible, different types of parking—on- and off-street, public and private—should be managed according to the same set of principles. Pricing, time limits, and payment mechanisms should be standardized as far as possible.
- **Use parking as a tool to manage roadway congestion.** In dense urban districts, traffic congestion can become a serious problem. Cities can mitigate this problem by matching the total parking supply to the capacity of the roadway system.
- **Maximize the contributions of parking to good urban design.** With good design, parking facilities can contribute to, rather than detract from, the quality of the public realm.

Parking Policies and Incentives

This section details a set of policies, rule changes, and implementation strategies designed to create a market-based approach to parking management in the Kaka`ako district. Implemented fully, they will remove unnecessary incentives for driving, reduce traffic congestion, and improve the sense of place in the district. The section that follows outlines a set of Transportation Demand Management (TDM) strategies that will reinforce the effectiveness of this approach to parking.

Manage On-Street Parking

- The primary management goal for on-street parking supply in KCDD is to optimize access for businesses that rely on short-term visitors. This can be done by making it as easy as possible to find a parking space near where customers want to go. By setting specific availability targets and adjusting prices, demand can be effectively managed so that when a motorist chooses to park, they can do so without circling in search of a space, generating unnecessary traffic and emissions.
- In an emerging rail station area, on-street supply must be carefully managed to ensure that all-day or commuter park-and-ride uses are not allowed and that local parking needs are not overwhelmed by demand for access to the rail system.
- A set of strategies for management on-street parking is presented below.

Strategy PT1 Price on-street parking to ensure availability

One of the best ways to balance parking supply and demand is to treat parking like any other scarce commodity, and require motorists to directly pay for use of a space. By setting a price for parking, a city can establish the "market value" for each parking space and adjust those prices depending on the level of demand. Just as hotel room rates increase or decrease based on availability, demand-based pricing for parking seeks to increase prices when and where demand is highest and reduce prices when and where demand is low.

An ideal occupancy rate for on-street, curb spaces is approximately 85% at even the busiest hour, a rate which leaves about one out of every seven spaces available. These rates provide enough vacancies that visitors can easily find a spot near their destination when they first arrive. For a given block or off-street facility, the "right price" is the price that will achieve this goal. This means that pricing should not be uniform: the most desirable spaces need higher prices, while less convenient lots are cheap or may even be free. Prices could also vary by season, day of week, or time of day. Demand-based pricing can result in the following benefits:

- Consistent availability and ease in finding a parking space
- Longer time limits, thereby eliminating the need to move a vehicle to avoid time restrictions
- Convenient payment methods (credit cards, pay-by-phone) that eliminate the need to "plug the meter" and make it easier to avoid parking tickets
- Reduced search time for parking, resulting in less local congestion and vehicle emissions
- Reduced illegal parking and improved safety and street operations
- A more equitable and efficient way to account for the real costs to a city for providing parking

New advances in parking meter technology, such as wireless "smart" meters, make demand-based pricing a feasible option and can dramatically increase motorist convenience.

Action PT1.1 Designate Zones and Monitor Parking Occupancies

HCDA will conduct an initial study of on-street parking supply, occupancy, and turnover. To aid in the understanding of these conditions, the district will be divided into functional parking zones as illustrated in Figure 8-3. Threshold parking occupancies should be established for each zone.

Once a baseline understanding of these conditions is established, HCDA will continue to monitor parking patterns on an ongoing basis, particularly as new development occurs and new residents and business move into the district. This information will be used to inform placement of parking meters, prices, and other regulations.

Figure 8-3 Potential On-Street Marking Evaluation Districts

SOUTH LAKE UNION DEMAND BASED PRICING IN A TRANSITIONAL DISTRICT

In 2005, Seattle's South Lake Union District was dominated by light-industrial land uses. However, the District was on the verge of a major transformation. A single developer owned large areas of the district and had an aggressive master plan to transform South Lake Union into a dense, mixed-use urban neighborhood. At that time, parking demands in the district were very similar to Kaka`ako today. All non-regulated parking was full at 7 AM, used by local workers and those parking and walking to downtown. Time limited parking was highly underutilized. Nelson\Nygaard developed an on-street parking study that balanced current demand with the needs of a growing district.

Curb parking in Seattle's South Lake Union District
Image from Nelson\Nygaard

The plan recommended metering the entire district with no time restrictions on parking, except in areas where there were existing retail businesses. Prices were set based on demand, so all day worker parking was allowable and comparable to market rates in off street facilities. City staff was allowed to adjust prices quarterly to ensure 10-15% of parking was available at all times. Time restrictions have been added as the district redeveloped and ground floor retail uses were established. The flexibility of this approach has allowed the city to collect valuable parking revenue and manage parking incrementally as various areas of the district developed.

Action PT1.2 Authorize Staff to Implement Parking Meters and Adjust Prices

HCDA will work with the County and City of Honolulu to establish an ordinance that authorizes managing the on-street parking supply to ensure availability. The ordinance will:

- Specify a target on-street parking occupancy of 85% on each block face.
- Implement paid parking using parking meters or pay stations where necessary to achieve the target occupancy rates.
- Specify the frequency for adjusting price schedules. Based on data collected through ongoing monitoring, staff will adjust meter prices as needed to achieve the target occupancies.

There are a variety of meter types and technologies, including single-space and multi-space models. At a minimum, the meters should incorporate credit card and pay-by-phone technology.

Action PT1.3 Implement a pilot test of metered pricing

Most of the district's on-street parking is either unregulated and fully occupied throughout the day, or subject to time limits, and very lightly used. This pattern of use suggests that there is significant demand for longer-term parking. Conversion of some time-limited space to metered parking may help to serve this demand while raising revenue. HCDA, in conjunction with the City and County of Honolulu, will implement a pilot program, converting some time-limited on-street parking to metered parking without time limits. Low prices should be set initially to gauge the strength of demand. The test could begin by adding meters to all on-street parking that is not yet metered in the area west of Cooke Street (labeled as Area 1 in Figure 8-3). The rest of the district could be monitored and considered for future implementation. If the pilot program successfully attracts parkers and raises revenue without negative impacts, it should be widened to include other areas.

Action PT1.4 Consider establishing Parking Benefit Districts (PBD)

While effectively managed on-street parking improves retail sales and economic vitality of business districts, business owners are often initially concerned about the effect that priced parking will have

on their competitiveness with malls and other locations that offer free parking. One way for parking reforms to win the support of business owners is to establish "parking benefit districts," a system that returns some or all parking meter proceeds to the immediate area in the form of improvements to the business district itself. Improvements may include street sweeping, pedestrian improvements, lighting, landscaping, or other improvements as selected by businesses located in the district. Besides establishing up-front buy in, Parking Benefit Districts give business owners a long-term stake in the success of parking management and reduce opposition to future price increases.

RECOMMENDED RULE CHANGES FOR KAKA`AKO

The following regulatory changes would govern regulation of on-street parking in the Mauka and Makai areas of Kaka`ako.

- **Regulation PT1.1:** Establish on-street parking occupancy target of 85% per block face.
- **Regulation PT1.2:** Implement parking meters where necessary to meet occupancy target (Specifies blocks where parking meters are permitted).
- **Regulation PT1.3:** Enable meters to adjust prices based on demand (Specifies maximum amount that prices can be moved within a specified time period).

SMART METERS IN HONOLULU

In June 2012, the City and County of Honolulu started a pilot test of new smart parking meter technology. Designed to be convenient for motorists, the meters are solar powered, and allow payment by phone or credit card. The test also includes vehicle detection sensors, which will be used to collected information about parking occupancy. Phase 1 of the pilot test included Honolulu Civic Center Garage, S. King St. and Punchbowl St. near the state capitol building, and Honolulu Police Department. In phase 2, the test was expanded to Chinatown and the Financial Districts. This or similar meter technology could be deployed elsewhere in Kaka'ako.

Locations for Honolulu's SmartMeter Pilot

Replace Off-Street Minimum Parking Requirements with a Market-Based Approach

Today, regulations specify the amount of dedicated off-street parking that must be provided by any land use in the Mauka or Makai districts. However, once on-street parking is effectively managed, off-street minimum parking requirements will no longer be needed to ensure availability. Instead, excessive off-street parking would only worsen traffic, and discourage developers, employers, residents and other property owners from implementing strategies that reduce traffic and parking demand. A new set of rules for off-street parking provision is presented below.

Strategy PT2 Remove minimum parking requirements

Under this strategy, minimum parking requirements would be removed for all development within Kaka`ako. Off-street parking could still be built, but developers would determine the quantity of parking based on their own analysis of what is economically feasible for their project and what they believe the true parking demand is to make their project viable.

This change would create a "free market" for parking that is more realistically determined by actual parking demand, as opposed to arbitrary parking standards. It would reduce development costs and provide additional flexibility to developers, especially on smaller lots or with historic structures. It would also help to ensure that existing parking supply is efficiently utilized before additional parking supply is built. Numerous cities around the world, including many in North America have eliminated minimum parking requirements in major districts, including Seattle, San Francisco, Portland, OR, and Vancouver, BC.

The following requirements would still apply to all parking built in the district:

- Any parking built would still be subject to the parking design standards outlined in the Mauka Area Rules.
- As described above, any amount of parking supplied above the existing minimum parking requirements would be subject to shared parking. In other words, HCDA could retain the current minimum parking requirements (as per the Mauka Area Rules) as maximum level of parking which can be built as private, single-use parking. Any parking above that level would be required to be managed as shared supply.
- As described above, the cost of all parking would be "unbundled" (paid for separately) from the cost of housing or commercial leases.

RECOMMENDED RULE CHANGES FOR KAKA`AKO

The following regulatory changes would remove minimum parking requirements throughout the Mauka and Makai areas of Kaka`ako.

- **Regulation PT2.1:** Minimum parking requirements in the Mauka rules (Section §15-217-63 (e)) are repealed.
- **Regulation PT2.2:** Minimum parking requirements in the Makai rules (Section §15-23-68) are repealed.

Strategy PT3 Include building area devoted to parking as part of the calculated Floor Area Ratio (FAR) for a proposed development project.

The land use guidelines outlined in Chapter 3 of this plan include permitted Floor Area Ratio for each development parcel. Space devoted to parking does not count toward the permitted FAR in the current Mauka/Makai rules. Under this strategy, parking would be counted towards FAR calculation. Developers would therefore have a choice between dedicating floor area to parking or to other active uses that enhance the development and generate revenue for the developer. Utilizing the market based approach, a developer would be free to determine the most profitable use of the available space. More detail on this recommendation is provided in the Urban Design section of this plan.

RECOMMENDED RULE CHANGES FOR KAKA`AKO

The following regulatory changes would remove minimum parking requirements throughout the Mauka and Makai areas of Kaka`ako.

- **Regulation PT3.1:** FAR allocations are inclusive of parking.

Shared Use Parking Regulations

Because many different land uses (a bank and a bar or restaurant, for example) have different periods of parking demand, they can easily share a common parking facility, thereby limiting the total number of spaces required to serve the demand for parking at any one time. Shared parking policies do not treat the parking supply as individual units specific to particular businesses or uses, but rather emphasize the efficient use of the parking supply by including as many spaces as possible in a common pool of shared, publicly available spaces.

Strategy PT4 Establish a "park once" district in Kaka`ako

The typical suburban pattern of isolated, single use buildings, each surrounded by parking lots, requires two vehicular movements and a parking space to be dedicated for each visit to a shop, office, or civic institution. By contrast, shared parking policies facilitate "park once" districts, in which motorists can park just once and complete multiple daily tasks on foot before returning to their vehicle. Overall, the benefits of fully implementing a "park once" strategy include:

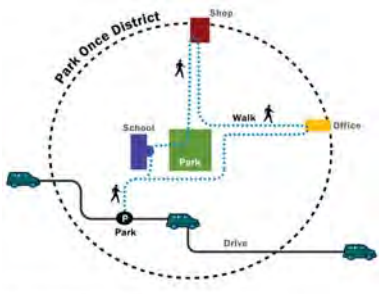

Image from Nelson\Nygaard
Based on illustration by Walter Kulash

- Reduced vehicle trips and required parking spaces because spaces can be efficiently shared between uses with differing peak hours, peak days, and peak seasons of parking demand.
- More welcoming environment for customers and visitors because they do not have to worry about getting towed for parking at one business while visiting another
- Allows for fewer, but more strategically placed lots and structures, resulting in better urban design and greater redevelopment opportunities
- By transforming drivers into pedestrians, who walk instead of drive to different destinations, shared parking can immediately activate public life on the streets and generate additional patrons of street-friendly retail businesses.

Outlined below are specific policy recommendations designed to facilitate shared parking and the creation of a "park once" district in Kaka`ako.

Action PT 4.1 Work with property owners and businesses to ensure that existing private parking is made available to the public when not needed for its primary commercial use

There are a number of steps that HCDA can take in encouraging existing property owners to make their parking facilities available for public use during off hours. One of the primary obstacles to this practice for many property owners is concern about liability. To eliminate this concern, HCDA (or the City/County of Honolulu) can work with developers and land owners to eliminate liability for public use of private parking. The City of Sacramento has successfully adopted this practice. In some cases, the HCDA or the City may also wish to take over operating responsibility for privately owned parking during periods of public use.

Seattle's ePark system directs visitors to the most immediate parking and tells them how many stalls are available.
Image from Nelson\Nygaard

Action PT 4.2 Maximize use of the existing parking supply by improving wayfinding and parking information

The HCDA should establish a wayfinding program specifically tailored to maximize utilization of the shared parking supply. Signs (including signs providing real time information, if necessary) can direct motorists to underutilized facilities, freeing up the most convenient "front-door" curbside spaces, and maximizing the efficiency of a parking system. Improved wayfinding in the form of new signs helps maximize the use of off-street parking facilities, representing another way to help eliminate traffic caused by cars circling for on-street parking. Wayfinding helps dispel perceived (but not actual) shortages in parking.

RECOMMENDED RULE CHANGES FOR KAKA`AKO

The following Code adjustments are recommended to promote shared use parking.

- **Regulation PT4.1:** Require that all newly constructed private parking provided in any Kaka`ako in commercial or residential developments in excess of *existing minimum parking requirements* be made available to the public.

  Discussion of regulation PT4.1: Under this regulation, developers would be permitted to build as much parking as the development requires. However, when parking is provided that exceeds the minimum requirements under today's regulations, the additional parking would have to be made available to the public. HCDA would work in partnership with developers to eliminate their liability for public parking on site. This arrangement would be particularly helpful, for example, in large residential developments with a significant number of non-resident owners. During periods of time when a small number of owners are on-site, the remaining number of parking spaces could be made publicly available. This reserve of parking could be used, for example, to provide park-and-ride access to the HART stations.
- **Regulation PT4.2:** Allow parking to be shared among different uses within a single mixed-use building by right.

Unbundled Parking

Parking costs are frequently subsumed into the sale or rental price of offices and housing. Although the cost of parking is often hidden in this way, parking is never free. Each space in a parking structure can cost $40,000 or substantially more. "Unbundling" these parking costs from the cost of other goods and services is a critical step for reducing parking demand and vehicle trips, because providing anything for free or at highly subsidized rate encourages use and means that more parking spaces have to be provided to achieve the same rate of availability. Further, by "daylighting" the cost of parking, new tenants may reconsider their need for multiple dedicated parking spaces.

Strategy PT5 Unbundle parking costs from housing costs

For both rental and for-sale housing in multifamily buildings, the full cost of parking should be unbundled from the cost of the housing itself by creating a separate charge. (The exception to this policy should be any new residence with individual garages, such as townhouses, rather than common, shared parking areas). Regulations should require that when residential parking is unbundled, it should be leased, rather sold, to homebuyers. While some homebuyers would shy away from purchasing a unit without parking included because of the fear that it could not be easily resold, a residential building with an available supply of leasable parking spaces allows the homeowner to acquire or forgo parking as their needs change.

This policy provides a financial reward to households that decide to dispense with one or more of their cars, and helps attract that niche market of householders who wish to live in a transit-oriented neighborhood where it is possible to live well with just one car or without a car.

Unbundling parking costs also changes parking from a required purchase to an optional amenity, so that households no longer have to pay for parking spaces that they do not need or cannot afford. This strategy also has significant potential rewards for the district as a whole: with lower rates of auto ownership, many households will shift trips to other modes of transportation, reducing total vehicle trips and total emissions.

RECOMMENDED RULE CHANGES FOR KAKA`AKO

The following Code adjustments are recommended to promote unbundled parking for housing.

- **Regulation PT5.1:** The cost of parking is required to be unbundled cost from the cost of rental housing.
- **Regulation PT5.2:** The cost of parking is required to be unbundled cost from the cost of ownership housing.

Strategy PT6 Unbundle parking costs from commercial leases

New commercial developments should be required to unbundle parking costs by leasing parking spaces separately from the commercial space, and should be required to allow employers to lease as few parking spaces as they wish. This policy also makes it easy for employers to implement a parking "cash-out" program. In a parking cash-out program, employees who choose not to drive to work are given a cash reimbursement instead of receiving subsidized parking from their employer. Employers can save money by leasing fewer parking spaces when fewer employees drive. The policy also makes it easier to institute shared parking arrangements, because building owners can more easily lease surplus parking spaces to other users.

RECOMMENDED RULE CHANGES FOR KAKA`AKO

The following Code adjustments are recommended to promote unbundled parking for commercial leases.

- **Regulation PT 6.1:** In commercial leases, parking must be included as a separate line item, with the quantity of parking to be leased determined by the lessee.

Tandem and Stacked Parking

Because of the difficulty of constructing underground parking in the district, a significant share of any parking constructed in Kaka`ako may be provided either as podiums at the base of buildings, or in surface lots, both of which can have significant negative impacts on the public realm. Tandem and stacked parking offer the opportunity to reduce these impacts by reducing the amount of surface area required to provide a given amount of parking. Given significant challenges to constructing underground parking in the KCDD, these spatial challenges associated with accommodating parking are particularly acute. High rise development will require up to five stories of parking to support development, if conventional parking design is used. Shrinking the footprint of parking using space-efficient parking strategies can conserve land for active public spaces and more productive land uses.

While the purpose of these strategies is similar, they are implemented differently:

- **Tandem parking.** Calls for an attendant to park two or more cars nose to tail, preventing all but the outermost car from leaving the parking facility independently; however, this allows more cars to fit into the lot by reducing the number of aisles required. In residential development, tandem parking is often unattended, with both parking stalls assigned to the same residence.
- **Stacked/robotic parking.** Stackers perform a similar function, but add vertical capacity; essentially, a hydraulic lifting apparatus raises the first car up, allowing a second car to be parked underneath. However the bottom car must be moved before the stacker can be lowered and the upper car released.

Generally applied in garages or parking lots, both techniques require an attendant to be on duty to move cars if a blocked-in car owner wishes to leave. These work well with valet systems and remote parking. It is important to recognize that these strategies do not reduce vehicle trips or traffic congestion because they do not reduce the total parking supply nor do they provide incentives to shift to other modes of transportation.

Figure 8-4 Robotic vs. Conventional Parking Structures

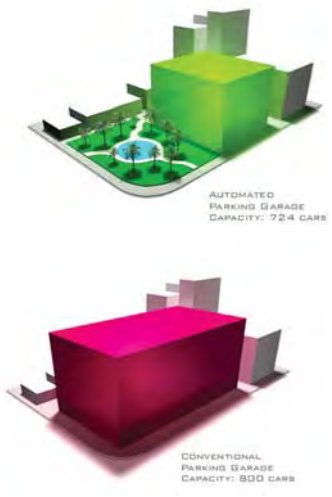

Image from Robotic Parking Systems

Strategy PT7 Tandem and stacked parking permitted by right

This strategy adjusts regulations in the Mauka and Makai Districts so that tandem and stacked parking are permitted by right. As discussed in Strategy PT3 and Regulation PT3.1, because space devoted to parking will be included as part of the permitted FAR for each development project, developers will have a strong incentive to minimize the amount of space dedicated to parking. Tandem and stacked parking offer a set of tools to help accomplish that objective.

RECOMMENDED RULE CHANGES FOR KAKA`AKO

The following Code adjustments are recommended to promote tandem and stacked parking.

- **Regulation PT7.1:** Regulation permitting tandem and stacked parking by right.

Transportation Demand Management Programs

Transportation Demand Management (TDM) refers to a collection of strategies to manage the demand for scarce parking and roadway capacity. They give people incentives to choose alternatives to driving alone by making those alternatives more attractive and convenient. TDM strategies are particularly appropriate for Kaka`ako because they are among the most cost-effective ways to accommodate higher density development without increasing traffic and parking demand. By investing in a strengthened package of parking and transportation demand management strategies, the HCDA can reduce growth in parking demand and decrease new vehicle trips associated with new development.

District Transportation Demand Management (TDM) Requirements

As urban living is making a strong comeback around the U.S., cities are looking to reduce traffic demand and to make streets friendly, livelier, and more social. To do so, many cities require mandatory transportation demand management actions from developers, employers, condominium associations, apartment buildings, and institutions, planned and instituted at the time of development. The TDM strategy for Kaka`ako will include the creation of a Transportation Management Association to promote, implement, and monitor TDM efforts; required TDM plans from all new development; and supporting infrastructure and programmatic investments by HCDA.

Strategy PT8 Establish a Transportation Management Association (TMA)

To encourage transportation Demand Management in Kaka`ako, HCDA should work to establish a Transportation Management Association (TMA). A TMA is a public/private partnership formed so that employers, developers, building owners, and government entities can work collectively to establish policies, programs, and services to address local transportation issues and foster economic development. TMAs are established within a limited geographic area to address the transportation management needs of their members. Their activities can be funded by member dues, transportation revenues from within the district (such as parking fees), or other sources. TMA's provide a variety of services that encourage more efficient use of transportation and parking resources. Such services can include:

- Access Management
- Advocacy
- Education and Outreach
- Flextime Support
- Guaranteed Ride Home Services
- Coordinated Incentive and Reward Programs
- Individualized Commute Trip Planning Services
- Marketing and Promotion
- Parking Management
- Pedestrian and Bicycle Planning
- Rideshare Matching and Vanpool Coordination
- Shared Parking Coordination
- Telework Support
- Transit Fare Products and/or incentives
- Transit Improvements
- Transportation Access Guides

In addition to developing and coordinating transportation management strategies, a TMA can bring a variety of stakeholders together to jointly address transportation challenges – and to give stakeholders a unified voice in advocating for enhanced transportation investments and coordination in their area.

Action PT8.1 Fund, market, and house a new TMA for the District

HCDA will provide initial start-up funding, marketing, and office space for a new TMA for the Kaka`ako district. As the TMA develops, ongoing funding may be obtained through membership dues, or rules could be established to fund the TMA through development fees and/or parking revenues. A

more detailed feasibility study and district outreach campaign would be needed to determine support and proper timing to develop and launch a TMA.

Strategy PT9 Require TDM for new residential developments

HCDA will require that each new multifamily residential development in the district join the TMA and develop a TDM Plan. A TDM Plan is a written document that outlines strategies, targets, and evaluation measures that will be taken to reduce single-occupancy vehicle (SOV) travel to and from the site. The plan should be created during the development process prior to project approval, and any programmatic elements should be carried out by the property manager (for rental properties) or homeowner's association (for condominium properties). These groups could either implement the elements of the plan themselves, or cede implementation activities to TMA staff. Residential developments will have the option of contracting with the TMA to create the TDM plan At a minimum, TDM Plans shall include the following:

- Project description; if this is provided in the land use application, the TDM Plan should reference the land use application
- The TDM strategies proposed for implementation (per Figure 8-5 below)
- Mode share performance targets
- A schedule for achieving mode share performance targets
- Copies of documentation to ensure deed notification of mandatory participation in the final TDM program to all subsequent purchasers and owners of the project.

TDM Plans shall identify strategies to achieve adopted mode split targets. The effectiveness of each TDM strategy varies based on land use, type of development (new or existing development), and geographic location. There is no single TDM measure that can effectively reduce a project's traffic impacts. As such, the HCDA can work with the applicant to develop a reasonable, relevant, and effective TDM Plan.

The TDM Program Strategies Menu in Figure 8-5 below provides a framework of options from which the TMA can help applicants identify appropriate actions to mitigate the traffic impacts of their project and sustain non-auto travel to the site for the lifetime of the building. TDM program strategies are organized by the type of program (i.e. incentive, programmatic, supportive facilities). In some circumstances, TDM strategies can be better implemented at the development phase (by a developer or property owner), while others will be implemented operationally for the lifetime of the project (by the property manager or homeowner's association). Depending on the type of project (location, new vs. existing construction, use), the TDM strategies selected will vary. This menu provides suggested strategies or guidance; it does not represent a comprehensive list of TDM strategies.

RECOMMENDED RULE CHANGES FOR KAKA`AKO

- **Regulation PT9.1:** New multifamily residential developments are required to create and implement a TDM plan that includes at least 5 elements from the checklist of TDM strategies, including at least one element from the 'Incentive' category.
- **Regulation PT9.2:** New multifamily residential developments are required to join the TMA.
- **Regulation PT 9.3:** Residential developments that are TMA members are required to monitor and report (every 5 years) on the status of any goals included in the TDM plan.

Figure 8-5 TDM Strategies Menu

	TDM Element	Program	Residential	Employer	Effectiveness	Strategy type
Incentive	Transit	Provide a subsidized or free transit pass	X	X	High	Operational
	Bike/pedestrian	Offer bicycle commuter benefit		X	Medium	Operational
	Carpool/ vanpool	Provide vanpool/carpool subsidy		X	High	Operational
	Parking	Charge market price for parking		X	High	Operational
	Parking	Offer parking cash-out program		X	High	Operational
Programmatic	Transit	Sell transit passes on-site	X	X	Medium	Operational
	Carpool/ vanpool/shuttle	Sponsor and community vanpool program through coordination, ridematching, and monetary sponsorship	X	X	Low-Medium	Operational
	Carpool/ vanpool/shuttle	Provide shuttle service between site and HART station	X	X	Low-Medium	Operational
	Carpool/ vanpool/shuttle	Provide carpool and vanpool matching services		X	Low-Medium	Operational
	Carpool/ vanpool/shuttle	Offer a guaranteed ride home program		X	Medium	Operational
	Peak hour trip reduction	Support telework or flexible work schedules		X	Medium	Operational
	Information access	Establish an on-site information kiosk with routes, schedules, and fares	X	X	Medium	Operational
	General	Develop "new employee" commute packet on transportation options		X	Medium	Operational
	General	Provide bike/car-share vehicles for worker errands		X	Medium	Operational
Supportive Facilities	Parking	Provide priority parking for carpools or vanpools		X	Medium	Development/ Operational
	Transit	Provide pedestrian-transit amenities such as shelters, sidewalks, footpaths, or signage on-site or close to the site	X	X	Medium	Development
	Parking	Limit on-site parking below existing minimum parking requirements	X	X	High	Development
	Bike/pedestrian	Provide on-site pedestrian circulation system connected to adjacent sidewalks or transit stops	X	X	Medium	Development
	Bike/pedestrian	Provide more bicycle parking than required in code	X	X	Medium	Development/ Operational
	Bike/pedestrian	Install end of trip facilities (lockers, showers, covered bicycle parking)		X	Medium	Development/ Operational
	General	Designate car-share spaces and bike share stations	X	X	Medium	Development/ Operational

Strategy PT10 Require TDM from large employers in new commercial development

HCDA should also require, as a condition of new development, that large employers (those with 50 or more employees) that are owners or tenants of new commercial developments in the district join the TMA and develop a TDM plan. Employers will have the option of contracting with the TMA to create the TDM plan. While commercial development will represent minority of new development permitted under the plan, these regulations can still have a significant effect, particularly on peak period vehicle traffic. Like residential TDM plans, the employer plans should include:

- Project description;
- The TDM strategies proposed for implementation (per Figure 8-5 above)
- Mode share performance targets
- A schedule for achieving mode share performance targets
- Copies of documentation to ensure deed notification of mandatory participation in the final TDM program to all subsequent purchasers and owners of the project.

Employers may select from the employer-specific TDM strategies listed in Figure 8-5 above. The TMA can help applicants identify appropriate actions to mitigate the traffic impacts of businesses and sustain non-auto travel for the lifetime of the building. TDM program strategies are organized by the type of program (i.e. incentive, programmatic, supportive facilities). In some circumstances, TDM strategies can be better implemented at the development phase (by a developer or property owner), while others will be implemented operationally for the lifetime of the project (by the property manager or homeowner's association).

RECOMMENDED RULE CHANGES FOR KAKA`AKO

- **Regulation PT10.1:** Large employers (50+ employees) are required to create, update (every 5 years) and implement a TDM plan.
- **Regulation PT10.2:** Large employers (50+ employees) who are tenants of new commercial developments required to join a TMA that would implement its TDM plan.
- **Regulation PT 10.3:** Employers that are TMA members are required to monitor and report (every 5 years) on the status of any goals included in the TDM plan

TDM Infrastructure and Public Investments

In addition to establishing the TMA and requiring TDM measures from new development, HCDA will pursue operational and infrastructure investments in TDM. These include measures to promote car-sharing and bike sharing, and establishing a multimodal wayfinding program. Bike share and multimodal wayfinding strategies and actions are described in greater detail in Chapter 5 and 6.

Strategy PT11 Promote car-sharing in Kaka`ako

Car-sharing is a "hassle-free" way to rent cars by the hour. Rather than being concentrated at a central location like a rental car company, car-sharing cars are dispersed throughout an urban area at convenient centralized locations, such as residential or commercial developments, civic buildings, or central parking facilities. Car-share operators use telephone and Internet-based reservation systems that are totally self-service. Members are charged hourly and sometimes mileage-based fees for their use and receive a single bill at the end of the month for all their usage.

In 2012, the University of Hawai`i at Manoa started a small car-share operation on campus. Here a car-share vehicle receives a traditional blessing on opening day.
Image from University of Hawai`i at Manoa

Special membership plans for businesses and organizations enable easy access for all employees, which can augment or replace fleet cars or use of personal vehicles for work trips. Car-sharing operators generally have a diverse fleet so that members have access to anything from a compact sedan to a pick-up truck. Car-sharing companies operate throughout the United States and around the world. Currently, two car-sharing companies operate in Hawai`i, each in a small number of select locations: WeCar (a subsidiary of Enterprise), and Greencar (an independent car-sharing company specializing in low-emissions vehicles. Neither company currently operates in Kaka`ako.

Car-sharing can have environmental, economic, and social benefits for both the individual user and for the transportation system and community as a whole. For individuals it can provide cost savings, greater mobility, and convenience. For the community, car-sharing can reduce car ownership and vehicle travel, thereby reducing parking demand, supporting more compact development, and reducing emissions. Car-sharing fleets also tend to be low-emission and fuel-efficient which augments the environmental benefits of reduced driving. Car-sharing offers particular promise for the tourism sector: for visitors who arrive on the island without their own vehicle, car-sharing offers the visitor the opportunity to have access to a car when needed without having to rent one for their entire stay. A hotel or resort could conceivably reduce its guest parking needs substantially by providing moderate size fleet of shared cars. Similarly, government entities could reduce their auto fleet and create a broader public benefit by transitioning some or all of their fleet to a publicly available car-share service.

Car2Go's fleet is comprised exclusively of branded Mercedes Smart cars, making them easy to identify. San Diego is the first U.S. city to launch an all electric Car2Go fleet.
Image from Car2Go

POINT-TO-POINT CAR-SHARING

Car2Go is one of the fastest growing car-share companies in the United States. Opening in several new major cities each year, the services unique one-way rental feature is proving very popular. Unlike services where a car is checked out and returned to the same location, Car2Go vehicles can be checked out using a magnetic access card, driven anywhere in the service area, and left in any publicly available on-street parking stall. Customers are charged only for the time in use, making short trips very affordable.

In order to help establish a car-sharing service in Kaka`ako, HCDA will pursue the following actions:

Action PT11.1 Recruit and provide incentives for car-sharing companies to operate in the district

Recruit an existing car-sharing service provider to expand into the Kaka`ako market. HCDA may consider partially or fully subsidize operation costs for a specified term to help these services begin operating. In the past, localities have encouraged car-sharing by providing minimum revenue guarantees for operators. This provides certainty for the operator, and costs the locality little or nothing if a market develops. HCDA may also wish to consider direct subsidies from sources such as revenues from parking fees or public facilities dedication fees.

Action PT11.2 Reserve some on-street parking spaces for car-sharing vehicles

HCDA will collaborate with the City to reserve a number of on-street parking spaces in strategic locations for car-sharing vehicles.

RECOMMENDED RULE CHANGES FOR KAKA`AKO

- **Regulation PT11.1:** Require that new residential developments with parking provide spaces for car-sharing vehicles.
- **Regulation PT11.2:** Require that visitor accommodations such as hotels and resorts provide developments with parking provide spaces for car-sharing vehicles [the ratio should be higher than for ordinary residential].
- **Regulation PT11.3:** Require that new commercial developments meeting certain requirements provide parking spaces for car-sharing vehicles.

DRAFT

APPENDIX A: STRATEGIES & ACTIONS

DRAFT

APPENDIX A: STRATEGIES & ACTIONS

Page

Chapter Three: Land Use

Strategy LU1 **Diverse residential building types, ground-oriented family housing in proximity to transit stations** ... **3-5**

Strategy LU2 **Reserved housing** ... **3-5**

Strategy LU3 **Transit-friendly land uses such as "third places," full-service grocery stores, cultural and community amenities** ... **3-6**

Action LU3.1 Prioritize capital spending for the placement of key community amenities within proximity to the station locations, including libraries, senior centers, and community centers. ... 3-6

Action LU3.2 Work with local developers and businesses to site a full service grocery store in Kaka`ako. The City's Primary Urban Center Plan points out that grocery stores require more floor area and service facilities than typical retail uses, warranting special incentives. ... 3-6

Action LU3.3 Explore impacts of hotel uses, and implement tools to ensure that Kaka`ako remains a district oriented with a local full-time residents rather than overwhelmed as a tourist destination. ... 3-6

Strategy LU4 **Creative uses, including interim uses, pop-up restaurants & food trucks, and artist interventions** ... **3-7**

Action LU4.1 Draft a "road map" how-to guide for temporary uses, particularly for sites undergoing construction or long-term redevelopment - so that properties can evolve while remaining active. ... 3-7

Action LU4.2 Ensure that the code allows for co-working spaces, live work and other flexible uses. ... 3-7

Action LU4.3 Include artist space, and/or arts community spaces as part of an optional bonus amenity in the incentive zoning system for added density. ... 3-7

Strategy LU5 **Adaptive re-use of character buildings** ... **3-8**

Strategy LU6 **Off-street parking utilization: "Right Size" parking supply for both commercial and residential uses by including parking in FAR** ... **3-9**

Action LU6.1 Parking supply may be phased or accommodated in satellite locations in order to provide additional flexibility. Phasing structured parking and alternately leasing a portion of parking from nearby surface lots can add to, or improve overall project feasibility. ... 3-9

Action LU6.2 Reinforce the policy that all spaces are used efficiently and reduce the need for single use reserved spaces in order to promote a district wide, park once strategy. ... 3-9

Action LU6.3 Consider working with developers and financiers to further explore options for sharing the financing of a new parking structure. ... 3-10

Action LU6.4 Clearly communicate the per-unit cost of a parking space to consumers. "Unbundling" allows an optional purchase or temporary rental of a stall enables drivers to make a more rational assessment of parking costs. ... 3-10

Page

Chapter Four: Urban Design

Strategy UD1 **A high-rise neighborhood with a variety of development types** ... **4-7**

Strategy UD2 **Encourage climate responsive design** ... **4-9**

Strategy UD3 **Provide for sunlight access** ... **4-10**

Strategy UD4 **Introduce design review** ... **4-11**

Action UD4.1 Implement a design review program for TOD Supplementary density buildings with guidelines that address site planning and massing, architectural building expression, streetscape, public amenities, and vehicular access/parking. ... 4-11

Action UD4.2 Establish design guideline principles and collect a set of precedent project images, diagrams and/or case studies showcasing of exemplary buildings and solutions for Kaka`ako. ... 4-11

Chapter Five: Mobility & Access

Connectivity

Strategy MA1 **Provide fine-grained street networks** ... **5-17**

Action MA1.1 Design block patterns to create a connected grid of streets that minimizes travel distances between points ... 5-17

Action MA1.2 Ensure that large developments provide internal streets and/or pedestrian connections that support the TOD Overlay Plan circulation network and which are permeable for public use by pedestrians, cyclists, and emergency vehicles ... 5-17

Action MA1.3 Design surface lots in the interim for efficient and comfortable pedestrian movement ... 5-18

Strategy MA2 **Plan for coordinated, multimodal transportation networks** ... **5-18**

Action MA2.1 Classify streets by their level of priority for vehicle, transit, and goods movement, and also for bicycle and pedestrian travel, and apply street design and performance standards to match these levels of priority ... 5-18

Strategy MA3 **Manage delivery and parking access to reduce conflicts with pedestrians and optimize the efficiency of the street network** ... **5-19**

Action MA3.1 Designate parking access and loading streets and require developers to provide ingress and egress from minor local streets ... 5-19

Action MA3.2 Encourage design that minimizes curb-cuts on all streets, particularly for high volume uses such as parking garages ... 5-19

Strategy MA4 **Make walking and cycling access to frequent transit as direct as possible** ... **5-20**

Strategy MA5 **Implement a coordinated multimodal wayfinding program** ... **5-20**

Action MA5.1 Establish a wayfinding program and study needs ... 5-22

Action MA5.2 Implement a wayfinding strategy ... 5-22

Pedestrian

Strategy MA6 **Create a well-connect pedestrian network** ... **5-27**

Strategy MA7 **Ensure that walking is safe and comfortable for everyone, everywhere in KCDD** ... **5-27**

Action MA7.1 Develop standards for safe and comfortable sidewalks and pedestrian crossings ... 5-27

Action MA7.2 Apply Universal Design principles to ensure that Kaka`ako is accessible to people of all ages and abilities ... 5-28

Page

Action MA7.3 Develop a district-wide traffic calming plan ... 5-29
Action MA7.4 Develop criteria to prioritize investment in pedestrian facilities ... 5-30

Strategy MA8 Design buildings and public spaces to support a safe and comfortable walking environment in Kaka`ako ... 5-31
Action MA8.1 Facilitate Crime Prevention through Environmental Design (CPTED) principles in the maintenance of landscaping and building design standards ... 5-31
Action MA8.2 Integrate high quality pedestrian design into the interim use of surface parking lots ... 5-31
Action MA8.3 Minimize curb cuts ... 5-32
Action MA9.1 Encourage active sidewalks and transparent building facades ... 5-32
Action MA9.2 Make alleyways and other public spaces district-wide "programmable" ... 5-32
Action MA9.3 Provide street trees, weather protection, and other amenities ... 5-32

Transit

Strategy MA10 Maximize the value of HART rapid transit by providing high quality access to the line/stations ... 5-37
Action MA10.1 Continue to collaborate with regional transit partners to ensure transit stops, stations and facilities are designed to ensure seamless transitions between transit modes and quality pedestrian-oriented places. This should include incorporation of guidelines for passenger facilities ... 5-39
Action MA10.2 Fund and implement a Downtown/Kaka`ako/Ala Moana circulator that enhances access to HART stations and key KCDD destinations and those in adjacent districts ... 5-39
Action MA10.3 Develop a longer-term plan for a higher capacity street-level circulator system ... 5-40

Strategy MA11 Support reliable bus operations in the KCDD ... 5-46
Action MA11.1 To the extent practical and based on funding availability, work with DTS to eliminate transit delay and improve transit reliability on regional and connecting transit streets through physical and policy improvements ... 5-46

Strategy MA12 Increase transit ridership for all types of trips ... 5-47
Action MA12.1 Around rapid transit stations and major bus transfer points, prioritize land uses and patterns that generate high transit ridership ... 5-47
Action MA12.2 Provide developer incentives to improve bus facilities adjacent to new development: Improvements could include new bus shelters, wider sidewalks, concrete bus pads, benches, changeable message signs, secure bike parking, bike-share stations (where appropriate), and trash receptacles ... 5-47
Action MA 12.3 Encourage schools and major employers to provide prepaid access on the TheBus and HART systems for all of their students and employees ... 5-47

Bike

Strategy MA13 Create a complete network of high-quality bicycle facilities, including a minimum of one new mauka - makai and one Ewa - Diamond Head protected bicycle facility, with the aim of increasing the number of people who use bicycles for everyday transportation ... 5-51
Action MA13.1 Develop a complete network of cycling facilities in KCDD, including at least one Ewa – Diamond Head and one mauka – makai direction protected bicycling facility ... 5-51
Action MA13.2 Promote HCDA as a cycling district ... 5-57

Page

Action MA13.3 Work with local partners to develop a bike share system in Kaka`ako and adjacent districts of Honolulu ... 5-59
Action MA13.4 Improve access to bicycle parking and require new development to include bicycle storage ... 5-67
Action MA13.5 Work with the City and County to fund and construct the Kaka`ako element of the citywide bicycle network (O`ahu Bicycle Plan) ... 5-68

Strategy MA14 Create a safe, comfortable cycling environment in Kaka`ako through facility design and public education ... 5-68
Action MA14.1 Create a destination-oriented bikeway signage and wayfinding system to direct riders to bikeways and major destinations such as hospitals, schools, shopping districts, bike parking, and bike share/rental and repair locations ... 5-68
Action MA14.2 Fund, construct and ensure operation of bicycle-transit centers at rapid transit stations (e.g., Bikestation model), which provide amenities such as secure bike parking, bike repair, and transit information ... 5-69

Auto

Strategy MA15 Manage traffic to allow regional mobility and local access while limiting impacts to livability in the KCDD ... 5-71
Action MA15.1 Strive to maximize the efficiency of the existing automobile infrastructure and manage major boulevards and commercial avenues so that they provide shorter travel times than parallel residential avenues or mixed use streets ... 5-72
Action MA15.2 Develop a network of local access streets to promote delivery, parking, and loading off primary mobility streets ... 5-73

Strategy MA16 Provide a safe environment for all road users. ... 5-73
Action MA16.1 Use traffic controls and design features to encourage motorists to drive appropriately for the type of streets they are using ... 5-73
Action MA16.2 Manage automobile speeds on major boulevards and district avenues to ensure comfort and safety for other roadway users ... 5-73

Strategy MA 17 Encourage a more sustainable transportation system ... 5-74
Action MA17.1 Promote public and private efforts to transition to clean vehicle fuels and technologies—especially emissions-free electric power ... 5-74
Action MA17.2 Develop "plug-in" electric vehicle charging stations throughout Kaka`ako ... 5-74

Chapter Six: Complete Streets in Kaka`ako

Strategy CS1 Preserve current levels of auto mobility on major regional thoroughfares ... 6-6
Action CS1.1 Increase district access using spatially efficient modes such as walk, bike, and transit ... 6-6
Action CS1.2 Focus on the right kind of development, in the right locations, with the right system, parking, and demand management tools in place ... 6-6

Strategy CS2 Limit right-of-way expansion to new street connections, redevelopment setbacks, and additional dedications for special pedestrian realm uses ... 6-6

Strategy CS3 Integrate Land Use and Building Form with Street Design and Programming ... 6-8

Strategy CS5 Establish a Complete Streets Typology and Design Guide ... 6-14

Strategy CS6. Establish Intersection Design Guidance ... 6-17

Page

Strategy CS7 **Establish performance measures/standards and decision tools that will incorporate Complete Streets 6-22**

Action CS7.1 Work with DTS to adopt transportation quality and level of service metrics that reflect the development of a walkable, multimodal transportation network 6-22

Strategy CS8 **Reallocate street space to better move people and activate KCDD pedestrian spaces 6-27**

Strategy CS9 **Strategically convert key multimodal streets from one-way to two-way operation 6-29**

Strategy CS10 **Redesign and operate intersections to accommodate all modes and reduce conflicts 6-30**

Action CS10.1 Design intersections to be compact and limited in complexity, where possible..... 6-30

Action CS10.2 Ensure crossings throughout the KCDD are as short, direct, and level as possible..... 6-31

Action CS10.3 Apply principles of universal design to ensure street environments and junctures are legibly and comfortably designed for pedestrians of all ages and abilities..... 6-31

Chapter Seven: HART Stations & Access

Strategy SA1 **Ensure high-quality pedestrian access to transit stations..... 7-4**

Strategy SA3 **Provide bicycle connectivity and storage..... 7-5**

Strategy SA4 **Provide for and manage vehicle access to transit stations..... 7-7**

Strategy SA5 **Ensure clear wayfinding in the station area. 7-7**

Strategy SA6 **Provide for universal access to transit stations..... 7-7**

Strategy SA7 **Implement actions specific to the Kaka`ako Station. 7-9**

Action SA7.1 Increase building setbacks along Ward Avenue to ensure sufficient sidewalk widths as redevelopment occurs 7-10

Action SA7.2 Design waiting areas and station plazas to safely accommodate potential crush loads during peak periods of travel and before and large events. 7-10

Action SA7.3 Introduce pedestrian countdown signals at all signalized intersections along Ward Avenue..... 7-10

Action SA7.4 Install a signalized crossing with countdown signal heads on the mauka side of the intersection of Ward Avenue and Halekauwila Street..... 7-10

Action SA7.5 Enhance the pedestrian crossing at the intersection of Ward Avenue and Ilaniwai Street..... 7-10

Action SA7.6 Provide new direct pedestrian connections from the Ward Neighborhood Master Plan's Central Plaza to the station..... 7-11

Action SA7.7 Minimize pedestrian and vehicle conflicts at ingress and egress points to the bus and kiss-and-ride turnaround facility..... 7-11

Action SA7.8 Integrate a bike share station into the Kaka`ako station design, and provide space for expansion. 7-11

Action SA7.9 Provide high quality separated bike facilities connecting to the station on Ward Avenue and Halekauwila Street..... 7-12

Action SA7.10 Provide high-quality shared bike facilities on Queen and Auahi Streets. 7-12

Action SA7.11 Increase supply of short- and long-term station bicycle parking at Kaka`ako Station..... 7-12

Page

Action SA8 **Implement actions specific to the Civic Center Station..... 7-12**

Action SA8.1 Establish Punchbowl Street as the primary pedestrian route between the station and local, state and federal campuses. 7-14

Action SA8.2 Enhance pedestrian experience along Halekauwila, Queen, and Pohukaina Streets..... 7-14

Action SA8.3 Improve pedestrian crossings in the Civic Center area by improving sightlines and shortening crossing distances..... 7-14

Action SA8.4 Provide interim pedestrian walkways and preserve long-term connections through the surface parking block on the makai side of Halekauwila Street..... 7-15

Action SA8.5 Integrate a bike share station into the Civic Center Station design, and provide space for expansion..... 7-15

Action SA8.6 Increase the supply of short- and long-term station bicycle parking at Civic Center Station. 7-15

Action SA8.7 Promote South Street as a major bicycle route accessing the station and institutional uses. 7-15

Action SA8.8 Provide separated bicycle facilities along Cooke Street..... 7-16

Strategy SA9 **Implement actions specific to Downtown Station (related to redevelopment of Aloha Tower portion of the District) 7-16**

Action SA9.1 Implement Connectivity Improvements from the Downtown Framework Plan 7-16

Action SA9.2 Create a seamless and inviting pedestrian connection between Downtown and the Aloha Tower area 7-18

Strategy SA10 **Collaborate with HART in order to integrate station design with TOD sites and catalyze redevelopment..... 7-25**

Action SA10.1 Work with agency partners to plan transit stations and associated infrastructure that are attractive public destinations, are integrated with the public realm and promote ridership..... 7-25

Action SA10.2 Develop strategies for private-sector engagement with partnerships, demonstration and/or catalyst projects to spur desired uses (see Chapter 3, page 3-19)..... 7.25

Action SA10.3 Provide a vision, design and principles for the station design, and support redevelopment with high trip-generating land uses (see Chapter 3, page 3-6)..... 7-25

Action SA10.4 Collaborate with jurisdictional and private sector partners to provide market-place comparable, such as the 690 Pohukaina joint-development project. (Chapter 3, pages 3-21)..... 7-25

Action SA10.5 Meet with local stakeholders to reinforce the benefits and opportunities of TOD, include financiers, lenders, property owners and developers..... 7-25

Action SA10.6 Partner to provide a vision for residual properties impacted by the rail, including clarifying liability. Consider a method, if necessary to land-bank residual properties resulting from construction areas for future high intensity development so they do not result in long-term underutilization..... 7-25

Action SA10.7 Continue to work towards the evolution of Kaka`ako District, including large and small scale redevelopment, master plans and priority complete streets and access upgrades as defined in this chapter 7.25

Strategy SA11 **Establish partnerships with key stakeholders to ensure successful station integration and TOD design..... 7-26**

Page

Chapter 8: Parking & Transportation Demand Management

Strategy PT1 **Price on-street parking to ensure availability** **8-5**
Action PT1.1 Designate Zones and Monitor Parking Occupancies 8-6
Action PT1.2 Authorize Staff to Implement Parking Meters and Adjust Prices 8-7
Action PT1.3 Implement a pilot test of metered pricing 8-7
Action PT1.4 Consider establishing Parking Benefit Districts (PBD) 8-7

Strategy PT2 **Remove minimum parking requirements** **8-9**

Strategy PT3 **Include building area devoted to parking as part of the calculated Floor Area Ratio (FAR) for a proposed development project** **8-9**

Strategy PT4 **Establish a "park once" district in Kaka`ako** **8-10**
Action PT4.1 Work with property owners and businesses to ensure that existing private parking is made available to the public when not needed for its primary commercial use 8-11
Action PT4.2 Maximize use of the existing parking supply by improving wayfinding and parking information 8-11

Strategy PT5 **Unbundle parking costs from housing costs** **8-12**

Strategy PT6 **Unbundle parking costs from commercial leases** **8-12**

Strategy PT7 **Tandem and stacked parking permitted by right** **8-13**

Strategy PT8 **Establish a Transportation Management Association (TMA)** **8-14**
Action PT8.1 Fund, market, and house a new TMA for the District 8-14

Strategy PT9 **Require TDM for new residential developments** **8-15**

Strategy PT10 **Require TDM from large employers in new commercial development** **8-17**

Strategy PT11 **Promote car-sharing in Kaka`ako** **8-17**
Action PT11.1 Recruit and provide incentives for car-sharing companies to operate in the district 8-18
Action PT11.2 Reserve some on-street parking spaces for car-sharing vehicles 8-18

DRAFT

APPENDIX B: RECOMMENDED RULE CHANGES

DRAFT

APPENDIX B: RECOMMENDED RULE CHANGES

Chapter Five: Mobility & Access

Connectivity

RULE CHANGES FOR KAKA`AKO

Create a Fine-Grained Street Network

- **Regulation MA1.1:** Related to internal connections for large developments, require pedestrian connections or service street between buildings where block lengths exceed 300 ft.
- **Regulation MA1.2:** Related to internal connections for large developments, require through-block pedestrian connections when a substantial portion of a block is developed with commercial projects or when the ground floor uses are largely commercial. In cases where adequate lot size exists to develop two commercial projects on a block, a through block pedestrian connection is required. Connections are required at mid-block and have a minimum clear dimension of 20 feet both horizontally and vertically.
- **Regulation MA1.3:** Require master plans and large developments to achieve an intersection density of 300 intersections per square mile or better, including shared streets, pedestrian ways of 20' or greater, and service alleys designed with adequate space for pedestrian movement.

Plan for Coordinated, Multimodal Transportation Networks

- **See Chapter 6**

Manage Delivery and Parking Access to Reduce Conflicts with Pedestrians and Optimize the Efficiency of the Street Network

- **Regulation MA3.1(a):** Apply Section 15-217-63-B (Parking Access) requiring parking access from an alley or service/parking access street to all parts of the KCDD. Require parking access from alley or service/parking access street for all development sites where 300' minimum street spacing requirements apply.
- **Regulation MA3.1(b):** Expand Section 15-217-63-L (Loading Access) of the Mauka Area Rules requiring on loading zones on thoroughfares and promenade streets to include avenues, particularly those designated for bicycle or high frequency transit uses; Include an exception process if the development site is not sufficient in size to allow an internal alley.
- **Regulation MA3.2:** Restrict curb cuts for drive-through on Commercial Boulevards and Avenues where reasonable alternative access is available; For drive-through uses, prohibit curb cuts and driveways used to approach and exit drive-through facilities, stacking areas for waiting vehicles, and the facility itself, such as a drive-up window or gas pump island.

Make Walking and Cycling Access to Frequent Transit as Direct as Possible

- **See Chapter 7**

Implement a Coordinated Multimodal Wayfinding Program

- **Regulation MA5.1:** Ensure wayfinding placement provisions in Figures PZ1-7 and FT1-12.
- **Regulation MA5.2:** Establish an additional general figure after Figure 1.16 in the Mauka Rules that identifies prospective wayfinding sign locations by type of sign.

Pedestrian

RULE CHANGES FOR KAKA`AKO

The following additions or modifications to the rules for pedestrian quality will govern new development:

- **Regulation MA6.1:** On commercial or mixed-use corridors, buildings are required to have entry points every 60 feet so that pedestrians have numerous opportunities to interact with semi-public spaces.
- **Regulation MA6.2:** Amend §15-217-63-B to encourage street life and to make sure shared parking is viable, parking garages are required to have pedestrian entrances and exits to the street.
- **Regulation MA7.1:** Per §15-217-63-B-1 and 2, parking garage access points must be oriented toward side streets or alleys (Local Streets) to reduce conflict between cars and pedestrians on busy streets.
- **Regulation MA7.2:** In commercial and mixed-use corridors, buildings are required to have at least 70% transparency for ground level frontages to create visual interest for people walking along commercial or mixed-use corridors per §15-217-55-M-6.
- **Regulation MA7.3:** Per §15-217-55-M-6, buildings are required to locate primary entrances along front façades, and locate loading docks or service entries off of street-facing façades.
- **Regulation MA8.1:** Amend §15-217-63-C to define maximum driveway density. Curb cuts and parking garages portals should be restricted to one every tenth of a mile (rounding down). This means some block will not include driveways. Parking garage entrances must be located at the rear or side of buildings accessible by Local Streets (per Chapter 6).
- **Regulation MA8.2:** §15-217-63-C-2 should be revised so that residential curb cuts may be no more than 10 feet wide per lane (two lane maximum at 20 feet) and 12 feet wide per lane (two lane maximum at 24 feet) for commercial curb cuts. This is intended to minimize the impacts to the pedestrian realm and to create more consistent walking paths.
- **Regulation MA8.3:** Amend §15-217-63-I to state that surface parking lots must be screened along the street with landscaping or architectural elements to reduce their visual impact.
- **Regulation MA9.1:** Amend §15-217-39-D-1-7 to include placements standards for bike parking in Figures PZ.1 though PZ.7
- **Regulation MA9.2:** In §15-217-39-D-1-7, change Figures 1.14 (pedestrian zone treatment) and 1.15 (pedestrian zone fixtures) to include acceptable applications, dimensions of bike share stations in the furniture zone and in the frontage zone where property owners integrate bike share stations into the design of setbacks.
- **Regulation MA9.3:** Amend §15-217-63-I to state that multi-story parking in active retail or commercial areas must be wrapped in active uses such as retail to screen parking from the street and to increase street-level activity.

Transit

RULE CHANGES FOR KAKA`AKO

HCDA does not have a direct role in delivering transit services or designing street rights-of-way to accommodate transit operations and passenger loading. However, as the KCDD redevelops, HCDA and its local developer partners will work closely with TheBus (City/County) and HART to ensure transit access and operational considerations are addressed early and throughout the development review process.

- **Regulation MA12.1:** Require developers to construct transit passenger facilities on public right of way where designated/or where there is an existing stop that will require replacement as new public facilities are constructed.

Bike

RULE CHANGES FOR KAKA`AKO

HCDA does not have a direct role in delivering transit services or designing street rights-of-way to accommodate transit operations and passenger loading. However, as the KCDD redevelops, HCDA and its local developer partners will work closely with TheBus (City/County) and HART to ensure transit access and operational considerations are addressed early and throughout the development review process.

- **Regulation MA12.1:** Require developers to construct transit passenger facilities on public right of way where designated/or where there is an existing stop that will require replacement as new public facilities are constructed.

Auto

RULE CHANGE FOR KAKA`AKO

HCDA does not currently regulate the design of traffic facilities in the public right-of-way. Regulatory changes are focused on encouraging developers to provide infrastructure that would help private consumers transition to more sustainable vehicle types.

- **Regulation MA17.1:** Related to the inclusion of EV stations, HCDA will develop rules to support HRS 291 requirements to include at least one EV charging station in publicly accessible parking garages over 100 stalls.

Chapter Six: Complete Streets in Kaka`ako

RECOMMENDED RULE CHANGES FOR KAKA`AKO

The following rules changes are recommended for various roadway and pedestrian design elements of the Mauka/Makai Rules. Additional rule changes will be proposed upon completion of HCDA's forthcoming Complete Streets Design Standards.

- **Regulation CS5.1:** Incorporate the Complete Street types as part of §15-217-38 through 39: The Thoroughfare Plan rules currently focus heavily on the pedestrian realm, so the rules should reflect street types design options, modal trade-offs, and general design guidelines.
- **Regulation CS5.2:** §15-217-39-D-1-7 updated to include allowances and design guidance for the "shared street" designs as part of the Local Streets street type (completed following completion of future HCDA Complete Streets design guide).
- **Regulation CS5.3:** To ensure predictable traffic movement and limit conflicts with pedestrians, parking access lanes, alley or any other Local Street types should be permitted to operate as one-way connection. Additional language should be added to §15-217-63 to clarify this provision.
- **Regulation CS7.1:** In a new section of the Rules, HCDA and DTS should jointly adopt and implement transportation quality and level of service metrics and data collection processes to track the benefits and impacts of implementing the Complete Streets strategy (completed following development of HCDA Complete Streets design guide)..
- **Regulation CS8.1:** Amend §15-217-39-D-1-7 to include the enhancement/buffer zone as part of the sidewalk zone nomenclature and include design elements and programming such as parklets, bike share docking stations, and in-street bike parking corrals.
- **Regulation CS10.3:** Include a new section in the Rules that specifies universal design guidelines based on the recently completed Public Rights-of-way Accessibility Guidelines (PROWAG).

Chapter 8: Parking & Transportation Demand Management

RECOMMENDED RULE CHANGES FOR KAKA`AKO

The following regulatory changes would govern regulation of on-street parking in the Mauka and Makai areas of Kaka`ako.

- **Regulation PT1.1:** Establish on-street parking occupancy target of 85% per block face.
- **Regulation PT1.2:** Implement parking meters where necessary to meet occupancy target (Specifies blocks where parking meters are permitted).
- **Regulation PT1.3:** Enable meters to adjust prices based on demand (Specifies maximum amount that prices can be moved within a specified time period).

The following regulatory changes would remove minimum parking requirements throughout the Mauka and Makai areas of Kaka`ako.

- **Regulation PT2.1:** Minimum parking requirements in the Mauka rules (Section §15-217-63 (e)) are repealed.
- **Regulation PT2.2:** Minimum parking requirements in the Makai rules (Section §15-23-68) are repealed.

The following regulatory changes would remove minimum parking requirements throughout the Mauka and Makai areas of Kaka`ako.

- **Regulation PT3.1:** FAR allocations are inclusive of parking.

The following Code adjustments are recommended to promote shared use parking.

- **Regulation PT4.1:** Require that all newly constructed private parking provided in any Kaka`ako in commercial or residential developments in excess of *existing minimum parking requirements* be made available to the public.

  Discussion of regulation PT4.1: Under this regulation, developers would be permitted to build as much parking as the development requires. However, when parking is provided that exceeds the minimum requirements under today's regulations, the additional parking would have to be made available to the public. HCDA would work in partnership with developers to eliminate their liability for public parking on site. This arrangement would be particularly helpful, for example, in large residential developments with a significant number of non-resident owners. During periods of time when a small number of owners are on-site, the remaining number of parking spaces could be made publicly available. This reserve of parking could be used, for example, to provide park-and-ride access to the HART stations.
- **Regulation PT4.2:** Allow parking to be shared among different uses within a single mixed-use building by right.

The following Code adjustments are recommended to promote unbundled parking for housing.

- **Regulation PT5.1:** The cost of parking is required to be unbundled cost from the cost of rental housing.
- **Regulation PT5.2:** The cost of parking is required to be unbundled cost from the cost of ownership housing.

The following Code adjustments are recommended to promote unbundled parking for commercial leases.

- **Regulation PT 6.1:** In commercial leases, parking must be included as a separate line item, with the quantity of parking to be leased determined by the lessee.

The following Code adjustments are recommended to promote tandem and stacked parking.

- **Regulation PT7.1:** Regulation permitting tandem and stacked parking by right.

Chapter 8: Parking & Transportation Demand Management (Continued)

RECOMMENDED RULE CHANGES FOR KAKA`AKO

- **Regulation PT9.1:** New multifamily residential developments are required to create and implement a TDM plan that includes at least 5 elements from the checklist of TDM strategies, including at least one element from the 'Incentive' category.
- **Regulation PT9.2:** New multifamily residential developments are required to join the TMA.
- **Regulation PT 9.3:** Residential developments that are TMA members are required to monitor and report (every 5 years) on the status of any goals included in the TDM plan.
- **Regulation PT10.1:** Large employers (50+ employees) are required to create, update (every 5 years) and implement a TDM plan.
- **Regulation PT10.2:** Large employers (50+ employees) who are tenants of new commercial developments required to join a TMA that would implement its TDM plan.
- **Regulation PT 10.3:** Employers that are TMA members are required to monitor and report (every 5 years) on the status of any goals included in the TDM plan.
- **Regulation PT11.1:** Require that new residential developments with parking provide spaces for car-sharing vehicles.
- **Regulation PT11.2:** Require that visitor accommodations such as hotels and resorts provide developments with parking provide spaces for car-sharing vehicles [the ratio should be higher than for ordinary residential].
- **Regulation PT11.3:** Require that new commercial developments meeting certain requirements provide parking spaces for car-sharing vehicles.

Executive Summary

The Kaka`ako Community Development District (KCDD) sits within a relatively low-lying coastal area of Honolulu. Existing work from University of Hawaii's Coastal Geology Group, the National Oceanic and Atmospheric Administration's Sea Level Rise and Coastal Flooding Impacts Viewer and Coastal Storms Sea Level Rise Study provide strong evidence that much of the KCDD will experience persistent flooding with a 1-meter sea level rise. This will be exacerbated with storm activity.

The development and redevelopment of the KCDD poses an interesting planning question because it is a highly used urban area that is proposed to undergo significant redevelopment. This study provides a review of issues and emerging "best practices" in adaptation to sea level rise in urban areas and how they might translate to the KCDD. It reviews Hawaii's climate change adaptation planning efforts and provides a detailed case study of New York City. New York City provides a comprehensive example of citywide adaptation planning, from vulnerability assessment to extensive plan-making. In addition, the region has been a focal point of the Federal government in response to recent disaster events. Key findings are as follows:

1) There is a need for a comprehensive vulnerability assessment and sea level rise mitigation plan for the KCDD. This should build on current estimates of *exposure*, as well as include *sensitivity* and, *adaptive capacity*. This will help to build understanding of "critical thresholds" in the impact of sea level rise to critical infrastructure and population, as well as inform risk and vulnerability in regards to new development.

2) The vulnerability assessment for the KCDD should be made public and widely available to developers, prospective home buyers/renters, and businesses. This would allow private developers and residents to more optimally respond to market signals in regards to risk. At a minimum, current studies about sea level rise in the greater Honolulu area should be shared widely.

3) There should be community engagement in building understanding of risk and resiliency. It is important to build understanding of community needs and willingness to accept risk as it relates to sea level rise, as well as have strong mechanisms to educate people on the expected impacts of climate change.

4) There should be a study estimating the potential costs of sea level rise to the KCDD (and benefits of a variety of adaptive measures). Key considerations are the use of appropriate flood-resilient building materials and design, upgrading of wastewater and drainage systems, as well as road maintenance. These costs, and their distribution, must be understood to aid long-term decision-making.

1. Introduction

Accelerated sea level rise is one of the most certain affects of global climate change (Nicholls et al., 2007). Sea levels are expected to rise by at minimum of 0.6m by 2100 (Nicholls et al., 2007) and an emerging planning norm is to prepare for 1m of rise by 2100 (Parkinson and McCue, 2011). Coastal areas will be exposed to increasing vulnerabilities from erosion and storm surges. This impact will be exacerbated in heavily populated and urban areas (Nicholls et al., 2007). Without appropriate adaptive measures, valuable coastal infrastructure will be damaged by sudden onset events like storms as well as from everyday issues like increased flooding.

There are a plethora of studies suggesting that adaption to sea level rise is important (see for example Johnson, 2007; Deyle et al., 2007, California State Lands Commission, 2009; EPA, 2009, Codiga and Wager, 2011). Many local governments are considering how to incorporate sea level rise in local planning processes. Challenges in implementation, however, exist due to perceptions of scientific uncertainty (Parkinson and McCue, 2011) as well as substantial differences in regional implications of global climate models (Whetton et al., 2012). This means that it is difficult for planners and policy-makers to understand the exact magnitude and timing of sea level rise in any specific locale. Another barrier to action for local government is that adaptation programs require considerable financing (Parkinson and McCue, 2011).

The Kaka`ako Community Development District (KCDD) sits within a relatively low-lying coastal area of Honolulu. The development and redevelopment of the KCDD poses an interesting planning question because it is a highly utilized urban area that is proposed to undergo significant redevelopment. It will be home to three future Honolulu Rail Transit stations. The Transit Oriented Development (TOD) Plan suggests an increase in mixed-use zoning, meaning there will be additional commercial as well as residential activity. Moreover, proposed new infrastructure encompasses high and mid-rise buildings, as well as smaller infrastructure like bicycle sharing stations and increasing public spaces (Sichter, 2013).

The TOD Overlay Plan for the KCDD adopts a planning horizon to the year 2035. While this is a common planning time frame, adapting to sea level rise requires taking a longer-term approach. The typical replacement time for urban infrastructure is about 70 years (Walsh et al., 2004) – well into the decades experiencing impacts from accelerated sea level rise.

This study provides a review of issues and emerging "best practices" in adaptation to sea level rise in urban areas and how they might translate to the KCDD. Section 2 reviews global and Hawaii-specific projections for future sea level. Section 3 identifies best practices in adaptation to sea level rise. Section 4 discusses climate

change adaptation planning efforts, with a case study of New York City. Hawaii's climate change adaptation plans are documented. Section 5 discusses the use and prevalence of sea level rise considerations within environmental review. Section 6 discusses the range of possible impacts to the KCDD. Section 7 provides concluding remarks on potential planning responses to sea level rise in the redevelopment of the KCDD.

2. Global and Local Sea Level Rise

There are two types of sea level rise. The first is global, or eustatic, mean sea level and the second is local relative sea level. Global mean sea level rise is systematically used for sea level rise projections because it most accurately reflects the elevation of sea level due to climate change (Williams, 2013). Local relative sea level includes a combination of phenomenon relating to regional and local geophysical and oceanographic factors (Williams, 2013).

Global Mean Sea Level Rise Projections

Global mean sea levels have been fairly stable for the past 3,000 years until mid-19th century. Global mean sea level in the 20th century began rising at an average rate of 1.7 mm per year and the current average rate is nearly double, at 3.1 mm per year (Williams, 2013). Scientists have shown that acceleration in global mean sea level rise is primarily due to the phenomenon of global warming, or human-induced climate change (Nicholls et al., 2007).

Projections of increases in global mean sea level vary. IPCC 2007 predicted a range of 0.18 to 0.59 meter increase (relative to 1980-1999) by the year 2100 (IPCC, 2007). However, this model excludes "dynamical changes in ice flow," or rapid glacial melting. As more information becomes available, particularly about the impact of glacial melting, it seems that actual increases are on the more extreme end of the spectrum. A more recent synthesis of the science suggests that planning for a range between 0.5 to 2 meters by the year 2100 is advisable (Williams, 2013). Though a range of 4 to 8 meters is possible by 2100, it is not likely until after the 2100 time frame (Williams, 2013).

Hawaii's Sea Level

Local factors affecting sea level are tremendously complex, including issues of land subsidence, isostatic adjustment of the earth's crust, tectonic forces, gravitational changes, ocean circulation and wind patterns (Williams, 2013). While understanding all of the components of local relative sea level would be ideal for planning purposes, it can be challenging to "down-scale" global climate models for regional predictions. This is a growing area of scientific inquiry. In addition, however, there has been global positioning system (GPS) monitoring of tide gauges

in Honolulu as well as data that goes back to the turn of the 20th century. Based on GPS monitoring, there was an increase of approximately 0.5 meters of mean sea level in Honolulu between 1905 and 2006, which amounts to a mean sea level rise trend of approximately 1.5 mm per year (NOAA, 2013). This is slightly lower than the global mean sea level rise of the 20th century. Whereas global mean sea level rose approximately 6 to 8 inches over the past century, Hawaii's sea levels rose approximately 6 inches (though it differs by island) (Codiga and Wager, 2011). That Hawaii's rate of sea level rise is lower than the global average is due to a variety of factors (Codiga and Wager, 2011) and is not necessarily evidence that it will remain so in the future.

In 2011, the University of Hawaii Sea Grant College Program Center for Island Climate Adaptation and Policy released the report *Sea-Level Rise and Coastal Land use in Hawaii: A Policy Tool Kit for State and Local Governments* (Codiga and Wager, 2011). Through consultation with local experts, and considering both global and local factors, Codiga and Wager suggest planning for sea level rise of approximately 1-foot by 2050 and 1-meter by 2100. This is much in line with the planning occurring in other places (see for example Parkinson and McCue, 2011).

Expected Impacts

Accelerated sea level rise will have a range of impacts on coastal areas depending on the topography. Most relevant to urban areas, sea level rise will exacerbate flooding due to poor drainage (Codiga and Wager, 2011). The level of the water table is largely determined by sea level. When the water table rises, existing gravity-driven drainage systems are expected to lose capacity and perform poorly. When coupled with events such as high tides, heavy rain and high surf, this may "lead to large-scale inundation of low-lying areas including coastal roads and Hawaii communities" (Codiga and Wager, 2011, p. 5). An increase in flooding is expected to increase costs for road maintenance (Parkinson and McCue, 2011), as well as for more resilient building design and materials. An example of an area in Honolulu in which this is already occurring during extreme high tides (coupled with heavy rain) is in Mapunapuna (Codiga and Wager, 2011). Continued sea level rise will aggravate coastal erosion and make existing sea walls and other protective measures inadequate (Romine et al., 2013). These effects together make nearby infrastructure and population more vulnerable in general and particularly so during storms.

3. Best Practices in Adaptation to Sea Level Rise

3.1. Typical Planning Responses

Planning responses to sea level rise are generally to *accommodate*, *retreat*, *avoid*, and *protect* (Walsh et al., 2004). These are all considered forms of climate change adaptation.

Accommodate means to continue occupation of the coastal area, but with adjustments to infrastructure and lifestyle. A common example is to alter building codes such that dwellings are raised enough to allow stormwater to travel beneath without substantive damage. Another example is the use of "green infrastructure" such as park areas that are designed to accommodate flooding.

Retreat is the antithesis of accommodate. It implies abandonment of the coastal area by moving infrastructure and peoples. This can mean both the moving of existing infrastructure as well as abandoning and rebuilding in less vulnerable areas. This can occur quickly or slowly, as well as dramatically change location or just mildly. A more mild form of retreat is simply to increase setback laws for new development. Other mechanisms include policies such as rolling easements and government purchase of vulnerable properties (California State Lands Commission, 2009).

Avoidance is a form of "slow retreat," where new development is not allowed in vulnerable coastal areas. Over time, as the old infrastructure reaches the end of its useful life, this effectively results in the relocating of infrastructure and peoples to less vulnerable areas.

Protection entails defending vulnerable areas with engineering-based solutions. This includes "soft" measures such as beach and dune restoration as well as more "hard" measures such as building seawalls, levees, and revetments. Enhancing drainage systems, for example through pumping, also offers a form of protection.

The decision to accommodate, retreat/avoid or protect really depends on the value of the threatened land (both natural ecosystems and built), the cost of protection, and the existence of other inhabitable areas (Parkinson and McCue, 2011).

Existing Urban Areas

There is a general notion that existing urban areas are best served by protection (Walsh et al., 2004). As an example, Wang et al. (2012) study the interaction of sea level rise, land subsidence and storm surges in the low-lying city of Shanghai, China. They find that under a moderate scenario of 0.4 meters of sea level rise by 2100 (i.e. not fully incorporating projections for accelerated sea level rise), half of Shanghai will be flooded and 46% of the existing seawalls and levees will be overtopped. Their recommendations include: improving municipal drainage systems, reinforcing sea embankments, and increasing the height of coastal seawalls and flood control levees (which are currently more than 6 meters high). In addition, in Shanghai, the rate of land subsidence can be reduced by limiting groundwater extraction and thus water management is a key component of mitigation.

However, a number of other place-specific studies bring into question the conclusion that urban areas necessarily benefit from protective measures. Parkinson and McCue (2011) provide an interesting example of the complexity in weighing the planning responses to sea level rise. In a vulnerability assessment for the City of Satellite Beach, Florida, the authors: 1) develop a three-dimensional model of the area, 2) compile and map critical infrastructure, and 3) quantify the extent to which the area and its critical assets would be submerged by rising sea level through the end of the century with a range of sea level scenarios (up to 1.8 meters). They find that Satellite Beach will lose 5% of its landscape as a result of 0.6 meters of sea level rise. An additional 20% of coastal land is lost with another 0.6 meters of sea level rise. This shows the non-linearity of the problem and demonstrates the "tipping point" between relatively benign and tremendously costly impacts. Seasonal flooding to an elevation of 0.6 meters is expected to begin in 2050 and thus the authors suggest the city has 40 years to develop and implement a successful adaptation plan. They conclude that, because the city is built on a segment of barrier island consisting of porous and permeable sand, increasing hydrostatic pressure from sea level rise will induce the flow of water through the sands. This will render the structures built to prevent flooding ineffective and thus the "engineered solutions employed or proposed to protect other Atlantic Coast cities from rising water will simply not work" (Parkinson and McCue, 2011, p. 221). However, the authors also state that retreat is also not a particularly viable local planning response because the limited availability of land at higher elevations. They suggest that pursuit of a retreat strategy would lead to development leaving the city limits.

Similarly, in a review of planning activities for sea level rise in Australia and New Zealand, Walsh et al. (2004) say that, "for urban areas, accommodation or abandonment is generally not a viable option, as the cost of the infrastructure to be abandoned is often too high" (p. 592). However, the authors go on to say that managed retreat may need to be considered in the long-term as other strategies become cost prohibitive. Protective measures can be thought of as short- to medium-term solutions.

Moreover, there is debate as to the merit of technologically-based solutions in relationship to flood management. There is a view that over-reliance on structural solutions can lead to even larger losses in the case of large storm events (outside of the intended design capacity) as well as encourage risky behavior when people feel more "secure" (Jeffers, 2013). These factors should be considered in any cost-benefit analysis determining the merits of protective measures.

New Development

There is also general agreement that new urban development is best in less-vulnerable areas. This can occur by increasing coastal setback laws and meeting of other development requirements based on vulnerability. However, accommodation

through improved building materials and design can help protect development from flooding and storm activity (California State Lands Commission, 2009). For new development in high-risk areas, the California State Lands Commission (2009) recommends development of expendable or moveable structures.

3.2. Assessing Vulnerability

There are a variety of ways to think about the vulnerability of infrastructure and peoples to natural surroundings. The Intergovernmental Panel on Climate Change (IPCC) defines vulnerability as, "the degree to which a system is susceptible to, and unable to cope with, adverse effects of climate change, including climate variability and extremes. Vulnerability is a function of the character, magnitude and rate of climate change and variation to which a system is exposed, its sensitivity, and its adaptive capacity" (Parry et al., 2007). By this definition, the main components are *exposure*, *sensitivity*, and *adaptive capacity* (Sahin and Mohamed, 2013). *Exposure* refers to incidence of physical impacts (such as sea level rise and storm activity) while *sensitivity* accounts for the interaction with human and natural systems (such is impacts to critical infrastructure or wetlands). *Adaptive capacity* refers to the ability of the system to respond.

A technocratic approach to assessing vulnerability focuses on measuring *exposure* and *sensitivity* to physical hazards and suggesting technologically-based solutions (Jeffers, 2013). This is the approach taken by Parkinson and McCue (2011) and Wang et al. (2012) in their studies of Satellite Beach, Florida and Shanghai, China, respectively. Due to the relatively straight-forward nature of the analysis, this is a common approach to assessing locational vulnerability to sea level rise and flooding.

Social scientists, however, continue to make the point that vulnerability is really the combination of the biophysical risk and the ability of peoples to react to it (Jeffers, 2013; Thatcher et al., 2013). Thus socio-economic factors are equally important (i.e. *adaptive capacity*). Though studies suggest a variety of ways to incorporate socio-economic factors of vulnerability, the lack of standardized methodology limits its widespread application (Jeffers, 2013). Understanding the social dimension is crucial, however, particularly in the case where the study area covers a widely heterogeneous population.

Several studies bring in economic considerations as a social dimension to understanding vulnerability. They find that it is the coupling of physical vulnerability with centers of economic development and critical infrastructure that lead to high levels of vulnerability. Thatcher et al. (2013) construct a Coastal Economic Vulnerability Index in a study of the Northern U.S. Gulf Coast. The index is based on 1-kilometer segments where socio-economic variables include population, urban land cover, and the economic value of key infrastructure (including residential and commercial buildings). This study builds on earlier work of Pendleton et al. (2010) that develop a Coastal Vulnerability Index, which focuses

solely on physical variables related to rising sea levels. For both studies, a 1-meter elevation threshold is chosen. The authors find that the most vulnerable areas result from a combination of physical vulnerability and a concentration of economically valuable infrastructure. They find that Lafourche Parish, Louisiana has the highest "index score" because of its energy infrastructure (deepwater oil platforms and refineries), high local shoreline erosion rates and high relative sea level rise. The authors find less vulnerable areas are characterized by low population density, urban development, and physical risk. The authors find that incorporating economic values into the vulnerability index substantially changes the results of the earlier study and would lead to different responses in terms of resource allocation for regional adaptation.

In an analysis of Norway, Aunan and Romstad (2008) find that the "extensive and well-developed infrastructure of roads, bridges, and ferries linking cities, towns and villages is likely to be negatively affected by sea level rise, particularly if this is concurrent with an increased risk and height of storm surges" (pp. 403). Densely populated areas, particularly with economic activities such as fishing, power production, and agriculture may experience considerable economic and material damage. Though the socio-economic impacts could be substantial in certain parts of Norway, particularly on the western coasts, they conclude generally that Norway as a whole "will *not* be seriously affected by accelerated sea level rise" primarily due to steep slopes and high elevation (pp. 403).

Economic vulnerability is, however, only one component of *adaptive capacity*. To develop a more holistic understanding requires knowledge of social networks and regional institutions (see discussion in Glaas et al., 2010). In a study on the vulnerability of Indian coasts to accelerated sea level rise, Kumar and Tholkappian (2006) use literacy and "spread of institutional set-up" as the social dimensions of *adaptive capacity*. These kinds of indices vary within the literature and are highly contextual.

3.3. Decision-Making Frameworks

The difficulty of decision-makers to proactively respond to accelerated sea level rise is often due to the complexity of environmental systems and conflicting viewpoints of stakeholders (Sahin and Mohamed, 2013). Because it is imperative that coastal communities respond to accelerated sea level rise, new decision-making models are warranted. Methods are emerging to help decision-making in the case of uncertainty.

Sahin and Mohamed (2013) suggest a Spatial Temporal Decision framework to assess coastal vulnerability and local adaptation alternatives. The decision-making framework combines a dynamic spatial model (physical and temporal) with a multiple-criteria-decision-aid approach. A multiple criteria decision model is a tool used to prioritize policy or planning actions, mainly through the eliciting of

information from stakeholders in a systematic and quantifiable way. The criteria used within this analysis are based on the *applicability*, *effectiveness*, *sustainability, flexibility*, and *cost* of a range of adaptation options; namely, *retreat*, *improve building design*, *improve public awareness*, *build protective structures*, and *take no action*. The Spatial Temporal Decision framework process consists of: 1) problem identification, 2) vulnerability assessment using the dynamic spatial model (which is a GIS analysis with a temporal dimension), 3) assessing adaptation strategies using the multiple criteria decision-making aid, 4) testing the preferred adaptation strategies chosen by the stakeholders to see if it provides an effective adaptation solution, and 5) refining the model and/or eliminating solutions that are shown to ineffective. It is an iterative decision-making framework working between physical and stakeholder-based information. In an application to the Gold Coat in Southeast Queensland, Australia, the authors find that residents are more likely to prioritize *improving building design* and to *build protective structures*. The least preferred option amongst residents is to *take no action* or *retreat*. Those deemed experts in the field, however, gave the highest priority to *improve public awareness*, then to *improve building design* and *retreat*. Politicians were found to prioritize *improving building design* and *retreat*. *Improving building design* was overall the adaptation strategy with most support. Interestingly, *effectiveness* and *sustainability* were found to be the two most important criteria among all stakeholder groups, while *cost* was the least. In addition, *improving building design*, which includes flood proofing, elevated building designs, and minimum flood levels, was found to provide more physical protection to vulnerable populations than *protective structures* such as sea walls within simulation analysis. However, this finding diminished greatly after a 1.5 meters rise in sea level.

In an ideal world, planners would like a projection for a particular rate of sea level rise associated with a certain probability (Walsh et al., 2004). Several studies have done a risk assessment, and estimated the probability distribution for a single outcome (Walsh et al., 2004). These are difficult, however, to use "off the shelf" for regional planning purposes. Generally, the range of sea level rise scenarios is not so cleanly linked to a probability distribution. In addition, the level of expert, policy-maker and stakeholder engagement required by Sahin and Mohamed's (2013) iterative decision-making approach may prove to be prohibitive from a cost and time perspective.

Alternatively, scenario planning is a way of building understanding of a range of outcomes (Moore et al., 2013). This also allows identification of "critical thresholds," where interactions with other regional factors make that level of sea level rise particularly damaging. A study by Zhang et al. (2011) on the impacts of sea level rise in the Florida Keys provides a good example. The authors find that 0.6 meters of sea level rise by 2100 would inundate about 70% of total land surface, 17% of population and 12% of real property. A 1.5 meters rise, however, would inundate 91% of the land surface, 71% of the population and 68% of real property. Although much of the land surface is affected in both scenarios, it is in the second scenario that residential and commercial areas are extremely impacted.

4. Climate Adaptation Planning in Hawaii and the U.S.

Climate Adaptation Planning includes risk and vulnerability assessments, identification of policies, prioritization of projects, funding and allocation of human and financial resources as well as the deployment of information sharing and decision-support tools (Cruce, 2009). The field of climate adaptation planning is relatively nascent and constantly evolving. The development of state and local climate adaptation plans varies widely, as the impacts that specific locations expect often drive the content, as well as any regional opportunities to mitigate impacts. This means that greenhouse gas emissions reduction strategies are sometimes included within adaptation plans. Fifteen U.S. states have completed Climate Adaptation Plans and four are in progress (C2ES, 2013). By this count, Hawaii is considered a State "in progress."

Whether states have officially completed an adaptation plan, coastal areas in the U.S. and around the world have been tremendously active in developing strategies to adapt to accelerated sea level rise. In fact, there are far too many to document and comprehensively review. Moreover, they vary widely in their reflection of regional needs and capacity. Common themes address issues of freshwater supply, flooding, wastewater management, transportation and building impacts (see Bloetscher et al., 2011; Deyle et al., 2007; and Johnson, 2000 for illustrative examples in Florida and Maryland). General responses range from outreach and education, improved building design and proactive zoning, realigning insurance and market incentives, to disaster recovery efforts.

This section highlights the activities of Hawaii and New York City (NYC) in climate change adaptation planning. NYC is perhaps the most illustrative example of comprehensive citywide adaptation planning, from vulnerability assessment to extensive plan-making. In addition, the region has been a focal point of the Federal government in response to recent disaster events. The Hurricane Sandy Rebuilding Task Force released their strategy report in August 2013.

For a more comprehensive list of climate change adaptation plans internationally, see the New York City Panel on Climate Change (2010), Appendix C.

4.1. Hawaii's Climate Adaptation Planning Processes

State Policies

In a publication by the Center for Island Climate Adaptation and Policy at the University of Hawaii Sea Grant College Program, it aptly says that, "adaptation is 'on

the radar' for state and local decision-makers…" (ICAP, 2012) – implying that both much has been and needs to be done.

In 2009, Act 20 created a Climate Change Task Force that was to identify adaptation actions for Hawaii. The Task Force was never funded or convened. It ceased to exist in 2011. Nevertheless, a series of stakeholder-driven workshops were held in conjunction with the *Ocean Resource Management Plan*, with funding support from the Army Corps of Engineers and the National Oceanic Atmospheric Administration, which resulted in *A Framework for Climate Change Adaptation in Hawaii* (ORMP, 2009). The framework suggests to:

1) Build a Climate Change Adaptation Team;

2) Develop and Adopt a Long-Term Vision;

3) Identify Planning Areas and Opportunities Relevant to Climate Change;

4) Scope Climate Change Impacts to Major Sectors;

5) Conduct a Vulnerability Assessment;

6) Conduct a Risk Assessment;

7) Prioritize Areas for Adaptation Planning;

8) Set Preparedness Goals;

9) Develop, Select, and Prioritize Preparedness Actions;

10) Implement Preparedness Plan; and

11) Monitor Progress and Update Plan as Appropriate (ORMP, 2009).

This provides the groundwork in determining key components of Hawaii's future climate change adaptation plan.

As a next step in creating overarching guidelines for adaptation in Hawaii, Act 286 was passed in the 2012 legislative session (Office of Planning, 2013). Act 286 aims to prioritize guidelines to prepare the State to address impacts of climate change. The priorities are to:

1) Ensure that Hawaii's people are educated, informed, and aware of the impacts climate change may have on their communities;

2) Encourage community stewardship groups and local stakeholders to participate in planning and implementation of climate change policies;

3) Invest in continued monitoring and research of Hawaii's climate and the impacts of climate change on the State;

4) Consider native Hawaiian traditional knowledge and practices in planning for the impacts of climate change;

5) Encourage the preservation and restoration of natural landscape features, such as coral reefs, beaches and dunes, forests, streams, floodplains, and wetlands, that have the inherent capacity to avoid, minimize, or mitigate the impacts of climate change;

6) Explore adaptation strategies that moderate harm or exploit beneficial opportunities in response to actual or expected climate change impacts to the natural and built environments;

7) Promote sector resilience in areas such as water, roads, airports, and public health, by encouraging the identification of climate change threats, assessment of potential consequences, and evaluation of adaptation options;

8) Foster cross-jurisdictional collaboration between county, state, and federal agencies and partnerships between government and private entities and other non-governmental entities, including nonprofit entities;

9) Use management and implementation approaches that encourage the continual collection, evaluation, and integration of new information and strategies into new and existing practices, policies, and plans; and

10) Encourage planning and management of the natural and built environments that effectively integrate climate change policy (HRS 226-109).

These priority guidelines are now "part of the statewide planning system, which coordinate and guides all major state and county activities and implements Chapter 226. As a priority guideline, climate change must now be considered in state and county budgetary, land use and other decision-making processes" (ICAP, 2012). However, actions may differ from the adaptation guidelines, in some circumstances, without penalty (ICAP, 2012). In addition, because the guidelines are at a relatively high-level, there is broad space for interpretation of what constitutes, for example, "encourag[ing] planning and management of the natural and built environments that effectively integrate climate change policy." The word "encourage" is non-binding while reference to effectively integrating climate change policy is vague, given there is currently little actual policy other than the guidelines themselves. These guidelines nonetheless serve as a foundational framework for prioritizing adaptation planning activities in Hawaii as well as for incorporating future climate change policies. The Office of Planning is "currently working with various

stakeholders, primarily through the *Ocean Resource Management Plan* program, to implement this policy" (Office of Planning, 2013).

County Setback Policies

Under Hawaii Revised Statutes (HRS) Chapter 205A, the Coastal Zone Management (CZM) law, the State governs activities that occur in coastal areas. The state shoreline setback is not less than 20 feet and not more than 40 feet inland from the shore (HRS 205A-42(a)). The authority to implement rules is given to the counties, including supplemental shoreline setback rules. Counties additionally govern coastal development by the issuance of Special Management Area (SMA) Permits and Shoreline Setback Variances (SSV).

Maui and Kauai counties in 2007 and 2008, respectively, implemented erosion-based setback laws. This is a form of *retreat* and *avoidance* for new development. Maui County's previous setbacks ranged between 25 and 150 feet depending on lot depth. For properties with an average depth of less than 100 feet, for example, the setback for development was 25 feet. Maui County's newer setback law takes the rate of erosion for the specified lot multiplied by 50 (years) with an additional 20-foot buffer. If this newly calculated setback is less than the previous one, the former is accepted.

Kauai County's shoreline setback line is the sum of 40 feet plus 70 (years) multiplied by the average annual erosion rate for the parcel (Codiga and Wager, 2011). The selection of seventy years reflects a finding that this is the average life-span of wood-framed coastal structures (Codiga and Wager, 2011). Kauai's rules provide for a 10% adjustment in the average annual erosion rate for future sea-level as well as a minimum buildable footprint allowance of 1,500 square feet. This is intended to avoid potential regulatory takings claims (Codiga and Wager, 2011).

For both the City and County of Honolulu and Hawaii County, the shoreline setback is generally a minimum of 40 feet. On Oahu, an exception is made in the case of small lots, in which the setback can be 20 feet. For new subdivisions, it is 60 feet (Hwang and Burkett, 2009). For a more detailed account of county shoreline setback plans and policies, see Hwang and Burkett (2009) and Codiga and Wager (2011).

Regional Plans

Several regional plans have begun to address issues of sea level rise. For example, the 2010 Hilo Community Development 5-Year Action Plan Update includes a strategy for including "sea level rise data in long-term implementation strategies" (Gagorik et al., 2010). In the 2012 Koolau Loa Sustainability Communities Plan update on Oahu, a new shoreline areas guideline is to, "evaluate emerging policies relating to climate change and sea level rise" (City and County of Honolulu, 2012).

More comprehensively, the 2012 Maui Island Plan acknowledges that sea level rise will affect Maui's coastal areas and that "prudent land use planning will consider possible sea level rise as a variable in the future." It includes a policy to develop plans that "encourage rebuilding inland as an alternative to shoreline hardening," "streamline the reconstruction of structures that are moved substantially inland," "encourage the relocation of existing structures so they are away from shoreline areas," and "encourage the relocation of vulnerable coastal roads." In addition, the plan says that coastal planning requirements must be updated to account for rising sea levels. These all fall under the objective of achieving "greater protection of life and property" (County of Maui, 2012).

ICAP Recommendations

In the Center for Island Climate Adaptation and Policy's study on *Sea-Level Rise and Coastal Land Use in Hawaii*, Codiga and Wager (2011) identify three main recommendations:

1) The governor or state legislature should direct state agencies to incorporate a sea-level rise benchmark of 1-foot-by-2050 and 3-feet-by-2100 in planning and permitting processes and decision-making, similar to the approach taken by the U.S. Army Corps of Engineers and to an executive order issued in California.

2) Scientific research must be expanded. Policy tools addressing sea-level rise derive legitimacy from the strength of the supporting science. Funding and support for continued scientific research, ultimately to establish site-specific estimates of sea-level rise impacts, is imperative.

3) A lead agency or task force, charged with initiating statewide adaptation planning to facilitate coordination and collaboration among various agencies and stakeholders, should be established. This entity will increase access to information, promote consistency among adaptation planning efforts, and create the statewide vision that is crucial to successful sea-level rise adaptation.

The first recommendation of setting a planning benchmark for expected sea level rise serves to empower existing processes, such as SMA and SSV permitting, to more keenly consider accelerated sea level rise in the granting/denial or mitigation/conditions of such permits. In addition, it might also support the systematic consideration of sea level rise within environmental review for projects within coastal areas.

The second recommendation is more general, but implies increasing capacity of researchers who conduct regional sea level rise and erosion analyses, such as the UH Coastal Geology Group and Sea Grant College. The third recommendation speaks to the larger need for the creation of a comprehensive adaptation plan.

In addition, Codiga and Wager (2011) identify planning, regulatory, spending, and market-based land use policy tools that state and local government in Hawaii should consider amending to address sea level rise. They are:

1) Planning tools include the Hawaii Coastal Zone Management Act, comprehensive plans, and pre-disaster mitigation plans.

2) Regulatory tools include zoning and overlay zones, floodplain regulations, shoreline construction setbacks, coastal construction control lines, hard armoring, rebuilding restrictions, building codes and resilient design, subdivision approvals, cluster development, land development conditions, **environmental review**, rolling easement statutes, non-structural armoring, and buffer zones [emphasis added].

3) Spending tools include capital improvement programs, land acquisitions, conservation easements, and rolling conservation easements.

4) Market-based tools include mandatory real estate disclosures, tax incentives, and transfer of development rights programs.

The identified tools can be implemented at both state and county government levels and requires policy change to fully utilize their mechanisms.

4.2. New York City: An Exemplary Case

NYC is emerging as a national and international leader in responding to climate change. Their climate change adaptation planning process to date is the most comprehensive of any U.S. municipality.

Projections suggest that NYC may face a 4-7.5°F increase in its mean annual temperature, a 5-10% increase in its baseline rainfall and 12-23 inches of sea level rise by 2100 (NPCC, 2010). This means that NYC's *exposure* to (slow and rapid) hazards is increasing as a result of climate change. As one of the world's densest cities, home to some of the world's most famous high-rise buildings, and with critical infrastructure like airports and subways within the current flood plain, NYC is highly *sensitive* to climate change impacts. NYC's general affluence means that at a citywide level it has a relatively high *adaptive capacity.* The ability of any individual person, household or business to adapt to sudden change, however, will vary widely and is difficult to capture on a citywide level. NYC's overall high level of adaptive capacity, however, means that much planning has already occurred on strategies to respond to accelerated sea level rise.

In 2004, the NYC Department of Environment launched a climate change adaptation initiative. A Task Force was created to ensure that departmental planning 1) take(s) into account the potential risks of climate change on the city's water supply, drainage and wastewater management systems, and 2) integrate(s) greenhouse gas emissions management (NPCC, 2010, pp. 19). The Task Force consists of over 40 public-and private-sector stakeholders. In 2008, the NYC Panel on Climate Change (NPCC) was created to assist the Task Force. It prepared a set of climate change projections for the NYC region as well as examined impacts to critical infrastructure (NPCC, 2010, p. 7). The NPCC was convened by Mayor Bloomberg and funded by the Rockefeller Foundation. The NPCC has produced a variety of reports, from technical risk and vulnerability analyses to a more comprehensive adaptation planning response. NPCC (2010) documents the series of vulnerability assessments completed in order to reach its' final recommendations. One of the particularly interesting analyses includes assessment of flooded areas in a 1-in-100 year flood zone with a variety of sea level rise scenarios (ranging from 9 to 53 inches). A major emphasis of impacts throughout the NPCC's documents is on the confluence of sea level, increased flooding and the incidence of extreme storm events. Expected impacts from accelerated sea level rise in NYC are:

Higher Average Sea Levels – *Highly Likely* (based on IPCC definition)

1) Encroachment of saltwater on freshwater sources and ecosystems, increasing damage to infrastructure not manufactured to withstand saltwater exposure.

2) Increase in pollution released from brownfields and other unprotected waste sites.

3) Inundation of low-lying areas and wetlands, and higher rates of beach and salt marsh erosion.

4) Increase of inflow of seawater to sewers and Wastewater Pollution Control Plants (WPCP) and reduced ability of discharging CSO and WPCP effluent by gravity.

5) Increase of salt front up the Hudson and Delaware Rivers, leading to reduced supply of drinking water.

More Frequent and Intense Coastal Flooding &
Shortened 100-Year Flood Recurrence Period – *Very Likely* (based on IPCC definition)

6) Increase in street, basement and sewer flooding.

7) Increase in flood risk to low-elevation infrastructure and wastewater treatment plants

8) Increase in delays on public transportation and low-lying highways.

9) Increase in structural damage to infrastructure due to flooding and wave action.

10) Increase in need for use of emergency management procedures.

The adaptation planning report, published in 2010, is particularly useful for understanding planning responses and policies to address sea level rise in a highly urbanized area. The major findings are:

1) New York City should begin to adapt to climate change today.

This speaks to the need to move forward even in the face of uncertainty. *Ad hoc* reactions to extreme climate events are found to not ensure long-term sustainability of the city.

2) New York City already faces a number of climate risks even without climate change as a factor.

The city is already quite vulnerable to disaster events, such as heat waves, storm surge, and floods, and this will just be further exacerbated by climate change impacts.

3) There is a potential for "tipping points" in the climate system, such as a rapid melt of polar ice sheets, which would have a great magnitude of consequence on the city.

This means that further monitoring is necessary to ensure that impacts can be properly assessed and with appropriate planning responses.

4) To effectively respond to climate change, the City should develop Flexible Adaptation Pathways.

This is a set of strategies that can evolve through updated climate risk assessments, evaluation of adaptation strategies and with additional monitoring. These pathways should be implemented by relevant agencies and organizations that manage the city's critical infrastructure.

The NPCC (2010) identifies eight recommendations for action. They are to:

1) Adopt a risk-based approach to develop Flexible Adaptation Pathways.

2) Create a mandate for an ongoing body of experts that provides advice and prepares tools related to climate change adaptation for NYC.

3) Establish a climate change monitoring program to track and analyze key climate change factors, impacts and adaptation indicators in NYC.

4) Include multiple layers of government and a wide range of public and private stakeholder experts to build buy-in and crucial partnerships for coordinated adaptation strategies.

5) Conduct a review of standards and codes to evaluate their revision to meet climate challenges.

6) Work with the insurance industry to facilitate the use of risk-sharing mechanisms to address climate change impacts.

7) Focus on strategies for responding to near- and mid-term incremental changes (e.g. temperature and precipitation change) as well as long-term low-probability, high-impact events (e.g. catastrophic storm surges exacerbated by sea level rise).

8) Pay particular attention to early win-win adaptation strategies (NPCC, 2010).

The issue of insurance is particularly interesting and an arena in which a large city, such as NYC, may have sway to change common practices. For example, the National Flood Insurance Program, while certainly successful at provided households in the U.S. flood insurance, is considered generally ineffective at (and perhaps even encouraging of) discouraging building and re-building in high-risk areas (Aerts and Botzen, 2011). The Biggert-Waters Reform Act of 2012 is an example of policy that aims to raise insurance rates for properties in high-risk areas.

Response to 2012 Hurricane Sandy

While no specific storm event can be attributed to climate change, the coupling of storms with sea level rise make coastal areas more vulnerable. Two recent events, Hurricane Irene in 2011 and Hurricane Sandy in 2012 underscore the importance of NYC's climate change adaptation plans and planning efforts.

Hurricane Sandy, that hit the U.S. East Coast on October 29, 2012, is responsible for the deaths of 159 people (Hurricane Sandy Rebuilding Task Force, 2013). It is estimated to have wrought $30 billion in total damages on the U.S. East Coast (Aerts et al, 2013, Appendix J) and another $30 to $50 billion in lost economic activity (Hurricane Sandy Rebuilding Task Force, 2013). There is an estimated two million working days lost. Hurricane Sandy is additionally considered the "worst disaster for public transit systems in the nation's history" (Hurricane Sandy Rebuilding Task Force, 2013). NYC's below ground subway system was shut down (in advance of the storm) and seawater breached into eight subway tunnels. Other major tunnels were breached. Floodwaters, storm runoff, wind damage and power outages contributed to the failure of wastewater treatment plants. Billions of gallons of raw and partially

treated sewage were sent into nearby waterways. Power losses led to the inability of drinking water utilities to provide potable water. In general, much of the economic loss is due to power outages and subsequent effects. Over 650,000 homes were damaged or destroyed (Hurricane Sandy Rebuilding Task Force, 2013).

In response, President Obama signed an Executive Order that established the Hurricane Sandy Rebuilding Task Force. The Task Force released its final report in August 2013. Within its' "rebuilding strategy" it identifies a number of ways in which government can better help communities respond to large disaster events. While the report is focuses on disaster mitigation, it acknowledges that "even a moderate amount of sea level rise will increase the flooding that coastal storm events cause" and thus the interaction between sea level and disasters is paramount (Hurricane Sandy Rebuilding Task Force, 2013, pp. 39). Nine recommendations have implications for areas coping with issues of sea level rise:

1) Giving governments and residents the best available data and information on current and future risks to facilitate good decision making for recovery and planning – for example, by creating and making widely available a Sea Level Rise projection tool.

This recommendation reflects the need for decision-makers to be able to properly assess risk and risk management in regards to coastal planning. A complementary recommendation is to develop a minimum flood risk reduction standard for major Federal investment, which has been adopted in application to projects funded by the "Sandy Supplemental."

2) Leveraging the Rebuild by Design competition to deliver innovative, resilient rebuilding ideas to the Sandy-impacted region.

This recommendation led to a regional design contest that aims to: "promote innovation by developing regionally-scalable but locally contextual solutions that increase resilience to the region, and to implement selected proposals with both public and private funding" (HUD, 2013).

3) Establishing guidelines to ensure those projects are situated and built to withstand impacts of existing risks and future climate change, in the region, and across the country.

4) Making housing units—both individual and multi-family—more sustainable and resilient through smart recovery steps including elevating above flood risk and increased energy efficiency.

These two recommendations are a move to performance standards for building and project resiliency. An example of such standards are, "how strong of a storm system [it] should be able to withstand," or "how long different types of customers can be without power" (Hurricane Sandy Rebuilding Strategy, 2013, pp. 49). While the

focus on the Task Force is on the New York/New Jersey region, the suggestion is to consider such standards nationally. While energy and energy efficiency are an important component of disaster resilience, it is not necessarily directly connected to issues of sea level rise.

5) Assisting States and localities to optimize Sandy recovery infrastructure funding and leverage non-federal resources to help build critical infrastructure assets that are resilient to current and future risks.

This recommendation, while broad, encompasses rebuilding energy infrastructure to be more resilient to disaster events. Other critical infrastructure includes water, transportation and buildings.

6) Encouraging homeowners and other policy-holders to take steps to mitigate future risks, such as elevating their homes and businesses above flood levels, which will not only protect against the next storm but also make their flood insurance premiums more affordable.

This recommendation encompasses issues like raising mechanical devices above expected flood level, wet floodproofing in a basement, and using water resistant paints/materials. The issue of insurance premiums is important in creating proper incentives for building and rebuilding, where a complementary recommendation is to continually assess decreasing premiums for mitigation activities (other than elevation, which is assumed to be effective).

7) Prioritizing the engagement of vulnerable populations on issues of risk and resilience.

8) Helping communities work together to be better prepared at a lower cost for the risks associated with a changing climate.

9) Supporting regional planning underway in New York and New Jersey to create and implement locally-created and federally funded strategies for rebuilding and strengthening their communities against future extreme weather.

These recommendations speak to the need to identify communities most at risk and to provide assistance in understanding vulnerability and appropriate responses. This can be done through planning. There are a number of regional programs, such as the New York Rising Community Reconstruction Program, which helps facilitate a collaborative community planning process. It identifies community needs and gathers data on technical assistance requirements. This kind of group can help to better understand community-level *adaptive capacity*. There are also regional economic development and planning efforts, such as the New Jersey Local Resilience Partnerships.

An interesting strategy identified by the Hurricane Sandy Rebuilding Task Force is land acquisition. In the case of repeated flooding, the report says that government and/or non-profit land acquisition can assist retreat from high-risk areas, and provide land for flood mitigation measures and/or natural areas. The Task Force recommends the Federal Government to consider coordinating the various Federal land acquisition mechanisms for this purpose. Many states also have land acquisition mechanisms.

Infrastructure Cost Implications

In response to the recent catastrophic storm events, Aerts et al. (2013) study the cost of a variety of flood management strategies in anticipation of the long-term sea level rise challenges of NYC. They are categorized into two main strategies: 1) the Resilient Open City and 2) Storm Surge Barriers. The Resilient Open City consists of measures that lower NYC's vulnerability by enhancing building codes and tailoring local-scale flood protection measures. The Storm Surge Barriers consists of building protective infrastructure. A summary of strategies and their related costs is provided in Table 1. Aerts et al. (2013) acknowledge that this provides preliminary cost estimates and that key adaptation categories are missing. Moreover, issues such as permitting are overlooked.

Table 1. Summary of Aerts et al. (2013) Strategies and Costs for NYC

	Description (for NYC and NJ)	Capital Cost	Maint. Cost
		$2012 Billion	$2012 Million
	Resilient Open City		
Strategy 1a	Enhancing building code measures in the 1/100 and 1/500 flood zones (elevation of the base floor of houses above base flood elevation; dry- and wet floodproofing for different heights; and applied to existing and new buildings).	$0.7-6.4B	$1M/year
Strategy 1b	Same as 1a, with additional protection of critical infrastructure. Includes local-scale adaptation measures including protection of power plants, water treatment plants, transportation infrastructure and medical facilities.	$10.9-15.1B	$2M/year
Strategy 1c	*Hybrid solution* anticipates uncertainty of future developments and combine elements of the Resilient Open City strategies with local scale protection measures. This includes no-regret measures that strengthen beaches through sand nourishment, protecting low-lying areas with levees (for example, in Red Hook, Hoboken and Manhattan); and measures that minimize environmental impacts such as maintaining salt marshes and wetlands.	$10.4-11.6B	$13.5M/ year
	Storm Surge Barriers		
Strategy 2a	E*nvironmental dynamics* strategy aims at maintaining the ecosystem functions of Jamaica Bay and its salt marshes through beach nourishment. The surrounding urban areas, including JFK airport will be protected by levees.	$18.9-23.1B	$98.5M/ year
Strategy 2b	In this scenario, sea levels have surpassed 1 meter +, meaning that it is no longer viable to maintain the Jamaica Bay wetlands. Instead, storm surge barriers will be installed across the Jamaica Bay Inlet. Similar to 2a, low areas will be protected by reinforcing bulkheads, levees or by landfill.	$17.9-23.8B	$126M/ year
Strategy 2c	Aims to reduce the length of coastline of the NYC area as much as possible. Rather than pursuing multiple barriers described in 2b, there is one barrier that connects Sandy Hook, NJ, and the tip of the Rockaways in Queens, NY. As in strategy 1c, lower sports on the inside of the protection system will be elevated.	$11.0-14.7B	$117.5M/ year

The costs for Strategy 1a are lowest because it includes only that of lowering vulnerability to buildings and not critical infrastructure. Additional protection leads to additional costs and, particularly, protective measures have tremendously high maintenance costs in comparison to flood-proofing. This constitutes solely a cost-analysis and not a more comprehensive cost-benefit analysis.

NYC is in many ways leading the way for climate change adaptation planning in the U.S. This is particularly so from a disaster management perspective. It is important to note, however, that their efforts frame disaster impacts related to more general

effects of climate change such as accelerated sea level rise. Due to geographical differences, the needs of different locations to develop local planning responses to climate change impacts will vary as well as the ability to adapt.

5. Considerations for Sea Level Rise in Environmental Review

Codiga and Wager (2011) suggest that environmental review is an appropriate regulatory tool in which to consider the impacts of accelerated sea level rise (a suggested 1-foot-by-2050 and 3-feet-by-2100 benchmark) in Hawaii. It suggests an update of Hawaii's Chapter 343 such that climate change impacts are considered. Similarly, NPCC (2010) suggests that New York State's Environmental Quality Review Act (SEQRA) and the City Environmental Quality Review (CEQR) are also well-poised to be amended to consider climate change impacts (NPCC, 2010, p. 95-97). Incorporating climate change (both adaptation and greenhouse gas emissions) within environmental review is becoming more widely considered and examples in practice are emerging. For example, the U.S. Army Corps of Engineers requires consideration of sea-level rise impacts to coastal and estuarine zones in all phases of its civil works programs (Codiga and Wager, 2011) and therefore leads to disclosure of such impacts in environmental review. Other agencies, such as the U.S. Department of Transportation, are undergoing comprehensive climate change adaptation planning (U.S. DOT, 2013).

The Center for Climate Change Law at Columbia Law School compiled a database of (NEPA-driven) Environmental Impact Statements (EIS) that address climate change. They collected 195 examples (up to the year 2011). Of them, five specifically consider sea level rise. Three of them are for the U.S. Army Corp of Engineers, one is for National Highway Traffic Safety Administration, and one is for the Bureau of Reclamation. As an example, a 2010 EIA for the U.S. Army Corp of Engineers assessed re-vegetation and restoration in Louisiana wetlands. While it is difficult to know whether this is an exhaustive sample, and determining that is outside the scope of this study, it nonetheless gives the impression that environmental review can be an appropriate tool in which to consider impacts of climate change – though its application is currently limited.

This is further evidenced by the lack of academic publication on the issue of climate change and environmental review. In one of the few peer-reviewed documents found as part of this study, Slotterback (2011) discusses emerging state-level environmental review practices for considering greenhouse gas emissions as a result of project implementation. Several states and agencies now systematically require consideration of greenhouse gases – though state environmental review laws are varied (see Slotterback, 2011, for a full discussion). No study on the systematic inclusion of climate change impacts to project outcomes is found. This is a fruitful area of future inquiry – particularly as agencies such as the U.S. Army Corp

of Engineers and a variety of municipalities continue to incorporate sea level rise into their planning practices.

It should be noted that the recently released Final Supplemental Environmental Impact Statement for the Turtle Bay Resort Expansion project on the North Shore of O`ahu addresses climate change impacts and suggests expanding coastal setbacks for development (Sichter, 2013).

6. Expected Impacts to the Kakaako Community Development District

The KCDD is bisected by Ala Moana Boulevard and its *mauka* (toward the mountain) area is bound by Piikoi Street, Punchbowl Street and King Street. On the *makai* (toward the ocean) side of Ala Moana Boulevard, the District is bound by the Ala Moana Regional Park and the property line between Pier's 2 and 4 at Honolulu Harbor. While no comprehensive vulnerability assessment exists for the KCDD, there are three existing studies and sources that suggest much of the KCDD will experience persistent flooding with a 1-meter sea level rise. The Coastal Geology Group at the School of Ocean and Earth Science and Technology at the University of Hawaii at Manoa has mapped a meter of sea level rise contour line (during high tide) in the broader Honolulu area (CGG, 2009). Much of the KCDD is within this zone; the entire *makai* area and much of the *mauka* area. The National Oceanic and Atmospheric Administration (NOAA) recently released their Sea Level Rise and Coastal Flooding Impacts Viewer (NOAA, 2013a). This maps between 1 and 6-feet of sea level rise throughout the U.S. Within Honolulu, while the map is at a relatively high level, it is possible to see the inundation of the KCDD. This is particularly evident through the region at an estimated 4-feet of sea level rise (relative to high tide). The map additionally shows that NOAA classifies the KCDD as medium-to-high in social *vulnerability.* Providing more context, a report released by the NOAA Coastal Storms Program (2013) looks at the impacts of a of 1-meter sea level rise coupled with additional flooding due to hurricane, tsunami and riverine overflow. The study covers the greater Honolulu area, from Pearl Harbor to Diamond Head. The 1-meter sea level rise is considered a baseline for analysis of storm events and thus it is not possible to isolate the mapping of 1-meter of sea level rise. However, given this has been done in previous studies, the added value is in building understanding the relationship between sea level rise and storm events. In the a rather hurricane storm surge and tsunami run-up "worst-case" scenarios, the KCDD is entirely inundated. Parts of the region would experience up to 10-feet of flooding. Within the greater Honolulu area, the study estimate that 87% of the tourism sector, 79% of construction and manufacturing activity, 75% of the health sector, and 81% of retail and wholesale activity are affected by the aggregate flooding. It is not estimated what proportion of the loss of economic activity occurs in the KCDD.

The KCDD's waterfront is generally a combination of sea walls and harbors. The two largest impacts to the KCDD as a result of accelerated sea level rise will likely

be: 1) more common and persistent flooding, and 2) coastal erosion and damage to protective structures and harbors. Flooding will likely be associated more with groundwater and seawater intrusion into the drainage system, resulting in upwelling from manhole covers, and localized flooding of certain streets (Rotzoll and Fletcher, 2012). However, in the long-term, storm surge overtopping existing seawalls may occur. Storm events will exacerbate flooding.

Persistent flooding within the KCDD will have the effect of 1) further challenging wastewater and drainage systems, and eventually rendering current systems inadequate and 2) causing damage to roads, buildings and other infrastructure (potentially subterranean utilities) not designed for flooding (with both rain and saltwater). The issue of wastewater will tax existing wastewater systems regardless of measures taken at the coast due to the interaction between the water table and storm activities. Damages to infrastructure like roads will require on-going maintenance. While the planned rail transit stations in the KCDD will be elevated, there may be impacts to connectivity with other modes of transportation.

Accelerated sea level rise will also impact existing sea walls, harbors/piers and other coastal infrastructure within the KCDD. The appropriateness of response is difficult to comment on without further analysis of existing infrastructure (like undertaken by the NPCC in NYC).

7. Recommendations and Conclusions

This study provides a review of best practices in regards to planning responses to accelerated sea level rise. The literature finds that the most vulnerable areas to accelerated sea level rise have high exposure coupled with a concentration of population and urban development. From the literature reviewed, best planning responses to accelerated sea level rise include: 1) prohibitive zoning in areas deemed vulnerable, constituting *retreat* and *avoidance*, 2) further pursuing protective measures such as improving drainage capabilities (including pumping) and hardened structures like heightening sea walls, and 3) accommodating flooding through improved building design (such as elevation). From the NYC case estimates, it seems that more "open strategies" like changes to building code have less upfront cost as well as ongoing maintenance costs, though there was little consideration to risk mitigation. The broader literature suggests that protective measures are good short to medium-term strategies, though may prove cost prohibitive in comparison to retreat in the long-run. In addition, the literature suggests it is best practice to *avoid* additional development in highly vulnerable areas. If development is allowed within the region, the development must follow best practices for resiliency to impacts such as flooding. California guidance has gone as far as to say that the buildings should be "expendable" or "moveable."

Kakaako is in a low-lying area of Honolulu, shown to be largely within the 1-meter contour line during projected high tide in the year 2100. According to the NOAA Sea Level Rise Viewer (2013), and at a relatively high level, flooding is most pervasive within the KCDD at 4-feet of sea level rise. The KCDD is an existing urban center that is being planned for urban redevelopment and densification. In terms of implications of sea level rise, planners and relevant agencies should consider several factors.

1) There is a need for a comprehensive vulnerability assessment and mitigation plan for the KCDD. This should build on current estimates of *exposure*, as well as include *sensitivity* and, *adaptive capacity*. This includes robust scenarios of future sea level rise and impacts to the KCDD. This will help to build understanding of "critical thresholds" in the impact of sea level rise to critical infrastructure and population, as well as inform risk and vulnerability in regards to new development.

2) At a minimum, information on sea level rise and vulnerability for the KCDD should be made public and widely available to developers, prospective home buyers/renters, and businesses. This would allow private developers and residents to more optimally respond to market signals in regards to risk (for example, to enhance building design). Education and outreach for the expected impacts to the KCDD are needed – particularly because no broader state level adaptation plan current exists.

3) There should be community engagement in building understanding of risk and resiliency. This is because the concept of vulnerability is somewhat relative – where it is important to understand community needs and willingness to accept risk, as well as have strong mechanisms to educate the community on expected climate change impacts. The iterative decision-making framework described by Sahin and Mohamed (2013) provides a comprehensive approach, though a more traditional scenario planning strategy can be employed.

5) There should be a study estimating the potential costs of sea level rise to the KCDD and detailed planning responses. Key considerations are the use of appropriate flood-resilient building materials and design, the upgrading of wastewater and drainage systems within the KCDD as well as road maintenance. Because Kaka`ako is an existing urban area, some of these costs would be born with or without redevelopment or densification. Costs associated with sea level rise will be distributed between state and county government, developers, residents, and taxpayers. These costs, and their distribution, must be understood to aid long-term decision-making. This study should be undertaken by an interdisciplinary team, including engineers, planners, architects and economists.

There is sound reason to adopt the sea level rise planning benchmark of 1-foot-by-2050 and 1-meter-by-2100 for Hawaii, based on the previous work of ICAP (Codiga and Wager, 2011). Moreover, there is strong evidence that much of the KCDD will experience persistent flooding by the year 2100 (CGG, 2009). Within the context of the KCDD, however, understanding the longevity of existing and new infrastructure is crucial to decision-making. Thus a study building understanding of the interaction between sea level, critical infrastructure and population is an important next step.

ABSTRACT

Pacific Legacy, Inc., under contract to Lee Sichter LLC, performed a Supplemental Cultural Impact Assessment (SCIA) for areas within the Kakaʻako Transit-Oriented Development (TOD) Overlay project area as described by the Proposed Action found in the project's Environmental Impact Statement Preparation Notice (EISPN) (Sichter 2012:1). The project area encompasses the Kakaʻako Community Development District (KCDD) as well as Aloha Tower Special District in the *ahupuaʻa* of Honolulu, Kona District, Island of Oʻahu, Hawaiʻi. The purpose of this SCIA is to identify cultural groups, resources, and areas of interest not addressed or not sufficiently covered by the existing record of cultural resources, which is based upon five Cultural Impact Assessments (CIA), two Ethno-Historical Inventory studies, and a Traditional Cultural Property (TCP) study that have been performed in the Kakaʻako area (UH 1978; Wilson Okamoto and Associates, Inc. 2002; McElroy et al. 2008; Spearing et al. 2008; Vogeler et al. 2010; Genz & Hammatt 2010; Elison and McElroy 2011; Maly et al. 2013). This SCIA builds upon these cultural investigations.

In general, cultural groups identified in previous cultural investigations included Native Hawaiians as well as *kamaʻāina* and cultural practitioners belonging to various ethnic groups and groups with mixed ethnicities. Practices identified consisted of a number of traditional Hawaiian activities and other activities that bind other ethnic and cultural groups together. Largely, traditional Hawaiian activities were not reported as being practiced in a traditional context. However, the reviewed CIAs demonstrate that in the distant past there was an abundance of tangible cultural resources, such as an array of fish, plants, salt, and ceremonial sites in the project area. Some of those resources are still available in a handful of locations, but far less in quantity. Further, intangible resources are still felt by Native Hawaiians who identify with the *inoa ʻāina* (Hawaiian place names) and *wahi pana* (storied places), due to the belief that *moʻolelo* (stories) and ceremonial practices have imbued the cultural landscape with the *mana* of their gods and ancestors. It is also well documented that *iwi kūpuna* (ancestral remains) and archaeological sites buried in this area are ubiquitous.

This SCIA has found that the vast area we now refer to as Kakaʻako has many cultures and sub-cultures. Kakaʻako also contains unique cultural resources, such as museums and art workshops, that attract people from all areas. While Kakaʻako has a rich and colorful past, people who live and work in Kakaʻako as well as those who travel from afar, have come to identify the area as having an evolving and multi-faceted culture. This culture features, among many, a progressive side and a side interested in preserving cultural traditions. Striking a balance between these two polar factions would support an affable cultural landscape.

A number of Kakaʻako's cultural practices and resources that were either overlooked or outside of the scope of previous CIA were identified in the course of this SCIA that occur in or adjacent to the Kakaʻako TOD Overlay project area. Cultural resources have been grouped as: Historic Places and Landmarks, Cultural Learning Facilities, Public Parks and Grounds, Memorials and Commemorations, Religious and Spiritual Gathering Places, and Public Art Installation and Entertainment Centers. These locations function as cultural resources in a sense that community members frequent them tap into the institutional knowledge held by members of the same cultural group or sub-group who also frequent the location in addition to the resource (i.e. memorials, art, music, and food) that they identify with. Further, regular and intermittent gatherings by those united by a common tradition, practice, ideal, identity, belief, and/or memory generates an institutional knowledge within the group and serves to perpetuate their cultural practices and values. In some cases, cultural resources are not necessarily tangible in nature, but are locations that serve as repositories for various shared traditions, practices, ideals, identities, beliefs, and memories. The cultural resources identified in this study are important facets of Kakaʻakoʻs cultural landscape, as they make Kakaʻako the contemporary cultural hub that it is today.

1.0 INTRODUCTION

A Supplemental Cultural Impact Assessment (SCIA) was performed by Pacific Legacy, Inc., under contract to Lee Sichter LLC, for the Kaka'ako Transit-Oriented Development (TOD) Overlay project area as described by the Proposed Action found in the project's Environmental Impact Statement Preparation Notice (EISPN) (Sichter 2012:1). The project area encompasses the Kaka'ako Community Development District (KCDD) as well as Aloha Tower Special District in the *ahupua'a* of Honolulu, Kona District, Island of O'ahu, Hawai'i [TMK: Aloha Tower Special District: 2-1-014:006; Kaka'ako: 2-1-015:009, 051, 052, 061-063; 2-1-029:001, 002, 010; 2-1-030:001, 003, 006-015, 017, 043; 2-1-031:001-005, 008, 010, 012, 015, 018-021, 024, 029-033; 2-1-032:001, 002, 007-012, 015, 017, 020, 022-024; 2-1-044:001-005, 022, 023, 032-034, 038-044, 046-048; 2-1-046:001-003, 005, 007-010; 2-1-047:001-006, 008, 010; 2-1-048:001, 002, 005-008, 022; 2-1-049:001, 003-005, 008-033, 037, 038, 040-043, 045-050, 054-061, 063-066, 068-076, 078-080; 2-1-050:001-004, 007, 009-025, 027, 028, 030-043, 045-050, 052-065, 067, 068; 2-1-051: 001-007, 010-014, 018, 019, 031, 033, 038, 040-044; 2-1-052:001-005, 007-013, 016, 017, 020, 022, 024, 027, 028, 031-036, 038-040, 042, 043, 045, 046, 051-054; 2-1-053:001, 030-032; 2-1-054:001, 021, 022, 025, 027, 028, 032, 033; 2-1-055:001-004, 006, 009, 017, 018, 021, 026, 032-035, 038; 2-1-056:001-004, 007, 008; 2-1-058:002, 006, 021, 035, 043, 048, 061, 069, 073, 088, 089, 094, 095, 099, 100, 101, 103, 105, 109, 124-128; 2-1-059:001, 003-006, 011, 013, 020, 021, 023-029; 2-1-060:001-009, 013, 015, 017; 2-3-001:001, 004; 2-3-002:001, 002, 057-059, 066, 067, 069, 086, 087, 104; 2-3-003:004-008, 011-015, 018-024, 026, 028, 030-034, 037, 038, 040, 043, 046-050, 052, 059, 061-069, 071, 073-075, 078, 080, 081, 083, 085-087, 089-095, 097-099, 103, 105; 2-3-004:002, 003, 007-010, 012, 025, 029, 031, 033-037, 039, 048, 051, 061, 065, 069, 071, 076, 079, 080; 2-3-005:001, 004-006, 012-017, 019, 022; 2-3-006: 001, 003, 004, 014-017; 2-3-007:023, 026-029, 033, 036, 039, 044, 045, 049, 054, 056, 057, 061-064, 066, 067, 069, 078, 091-093, 098-101, 104, 105, 107; 2-3-008:001-003; 2-3-009:001; 2-3-010:001-009, 011-028, 083, 092-094, 096-107, 111; 2-3-011:002-025, 029-051, 053, 054]. Specifically, the Kaka'`ako TOD Overlay project area consists of KCDD lands, which are comprised of 601.6 acres bounded by King Street to the north, Pi'ikoi Street to the east, Ala Moana to the southeast, Māmala Bay to the south, Pier 1 to the southwest, and Punchbowl Street to the west, as well as the HECO Downtown Power Plant block comprised of 3.4 acres bounded by South Nimitz Highway to the north, Richard Street to the east, Aloha Tower Drive to the south, and Bishop Street to the west (Figure 1). This SCIA proposes to identify cultural groups, resources, and areas of interest not addressed or not sufficiently covered by existing reports.

The Proposed Action in the Kaka'ako TOD Overlay EISPN is as follows:

> The Proposed Action is the implementation of a Conceptual Plan for Transit-Oriented Development ("TOD") within the Kaka'ako Community Development District (KCDD). The proposed TOD Plan will serve as an overlay on the existing rules governing development in the district, meaning that the existing rules remain in force and any proposed TOD development will be required to comply with the proposed TOD Plan. The implementation of Transit-Oriented Development is intended to maximize development in the district by promoting the use of smart growth principles, multi-modal transportation, and walkability (Sichter 2012:1).

1.1 PURPOSE

Over the last 150 years, the word "culture" has had many different meanings. For example, some people define culture as an appreciation of good literature, music, art, and food. A biologist, however, will use the term to refer to a colony of bacteria being studied. Anthropologists define culture in many ways as well, with a central definition of culture as the behavioral patterns of any group of humans that stem from learned behaviors. English Anthropologist, Edward B. Tylor, was the first to use the term in such a way in his book, *Primitive Culture* (1871). According to Tylor (1871:1), culture is "that complex whole which includes knowledge, belief, art, law, morals, custom, and any other capabilities and habits acquired by man as a member of society." Since Tylor's era, anthropology as a discipline has evolved and grown in complexity. Modern anthropologists understand that culture is constantly changing and that there can be many cultural groups within a society. Manifestations of these cultures can be seen in an array of material and non-material forms that are unique to a specific culture or sub-culture.

The term, "cultural resources" is also ambiguous in nature. Thomas F. King (2003), leader in historic preservation and federal cultural resource laws, vacillates on the definition of Cultural Resource Management (CRM) and holds that there is no agreement on the definition of CRM, but offers several stances on the definition for cultural resources by stating, "Some of us use the term broadly to refer to all elements of the physical and social environment that are thought by anybody – a community, a tribe, an interest group – to have cultural value" (King 2003:11). He later provides a counter perspective on cultural resources, which he holds is narrow and unfortunate. King states:

> Others define *cultural resources* much more narrowly – though the definition is often only implicit and not uncommonly denied. *Cultural resource* is taken by such people to mean a place that's eligible for the National Register of Historic Places or even just an archaeological site. This is unfortunate, because it makes it easy for government to ignore cultural resources that *aren't* archaeological sites or don't appeal to the keeper of the National Register and her staff and hence to allow their damage or loss without considering the feelings of those who value them (King 2003:12).

The purpose of this SCIA is to identify cultural resources and practices, in the broader sense, for areas in and around the Kakaʻako TOD Overlay project area that have not been identified by previously conducted CIAs. Due to its vast area, complex history, population density, as well as rapid land-use changes and urban sprawl, Kakaʻako currently has many cultures and sub-cultures that co-exist. There have been a series of demographic changes as well as land use changes in Kakaʻako since its initial pre-Contact settlement that have ushered in new groups and forced out others. In the last fifty years, cultural diversity in Kakaʻako has increased dramatically and is comprised of an array of ethnic groups as well as cultural groups bound by a common custom, belief, or "any other capabilities and habits," as Tylor (1871:1) states.

Native Hawaiians were the first to settle the area and, therefore, have the longest cultural history in the area. The primary focus of all previous cultural studies for Kakaʻako has been on Native Hawaiians. These assessments have provided us with a wealth of knowledge about past and present Native Hawaiian land-use of Kakaʻako, however, little attention was paid to other ethnic groups or other cultural groups. Further, no non-ethnic based cultural groups have been represented in previous studies. Many of the cultural resources identified in this study are of significant only to these "other" cultural groups and are contemporary in nature. It is important to note that cultural resources are no less important for cultural groups that exist today than those utilized by cultural groups in previous eras. Thus, efforts were made in this SCIA to include contemporary cultural resources and practices to be inclusive of all cultural groups in Kakaʻako and those that come from other areas to access these unique resources.

According to ACT 50, SLH 2000, an Environmental Impact Statement (EIS) "…should identify and address effects on Hawaiʻi's culture, and traditional and customary rights (ACT 50, SLH 2000: Section 1)." Essentially, a CIA, as a supporting document of the EIS, has the goal of promoting and protecting cultural beliefs, practices, and resources of "Native Hawaiians, other ethnic groups, and groups" (OEQC 1997:1). To date, the term "groups" has been left undefined by the 1997 Office of Environmental Quality Control (OEQC) Guidelines and Act 50, SLH 2000.

However, ACT 50, SLH 2000 goes to some length to stress the importance of this act in promoting and preserving cultural practices and resources of Native Hawaiians and other ethnic groups, stating:

> The legislature also finds that native Hawaiian culture plays a vital role in preserving and advancing the unique quality of life and the "aloha spirit" in Hawaii. Articles IX and XII of the state constitution, other state laws, and the courts of the State impose on government agencies a duty to promote and protect cultural beliefs, practices, and resources of native Hawaiians as well as other ethnic groups (ACT 50, SLH 2000: Section 1).

Yet, as declared in Act 50, SLH 2000, the legislation has the stated purpose to:

> 1) require that environmental impact statements include the disclosure of the effects of a proposed action on the cultural practices of the community and State; and
>
> 2) amend the definition of "significant effect" to include adverse effects on cultural practices.

The law remains unclear what defines "community and State" in terms of demographics and cultural groups or its sub-sets. "Hawaiʻi's culture"(ACT 50, SLH 2000: Section 1) and the community of Kakaʻako consists of many cultural groups, centered on common cultural values, beliefs, and interests, including (but not limited to) Native Hawaiian and other ethnic groups. Other cultural groups in the area (e.g. religious, arts, sports, political, commercial, etc.) are united as cultural groups by the special interest that they share, but rarely represent or consist of a single ethnic group. Additionally, these groups regularly commune and organize ceremonial and secular events; exhibiting various hallmarks of a distinct culture. Thus, a CIA should make every effort to include these groups and transcend the constraints of ethnicity. This document will assume "groups" include those bound by a common cultural interest, concentrating on those that are recognized as a distinct cultural group by the community.

1.2 METHODS

According to the 1997 OEQC *Guidelines for Assessing Cultural Impacts*, cultural practices and beliefs may include those relating to subsistence, commercial, residential, agricultural, access-related, recreational, as well as religion and spirituality. Further, the CIA is designed to promote and protect cultural beliefs, practices, and resources of native Hawaiians, other ethnic groups, and other groups (OEQC 1997: 3-4). To determine the effects of the proposed development on cultural practices and resources, the following tasks are undertaken:

> 1) identify and consult with individuals and organizations knowledgeable about cultural practices that may have taken place in the area;
>
> 2) conduct archival research about traditional practices that may have been conducted in the area;

3) describe the cultural practices that took place within the potentially affected area;

4) assess the impact of the proposed development on the cultural practices that may have taken place within the potentially affected area; and;

5) prepare a report on the findings resulting from the above investigations.

A copy of 1997 OEQC *Guidelines for Assessing Cultural Impacts* is provided in Appendix A.

To perform the Supplemental Cultural Impact Assessment (SCIA) a document search was conducted to identify any existing CIA performed in or around the Kakaʻako TOD Overlay project area. To do so, the Office of Environmental Quality Control (OEQC) and State Historic Preservation Division (SHPD) Library were researched to find any CIA conducted for the project area. All archaeological reports, Environmental Impact Statements (EIS), and Environmental Assessments (EA) pertaining to the general area of Kakaʻako were reviewed to determine if any CIA were conducted concordantly. A total of 5 CIAs previously conducted for the project area were identified and are as follows:

- Wilson Okamoto and Associates, Inc.
  2002 Cultural Impact Assessment in the Final Environmental Assessment University of Hawaii Health and Wellness Center. Prepared for the University of Hawaii, John A. Burns School of Medicine. Prepared by Wilson Okamoto and Associates, Inc., Honolulu.

- Spearing, Mishalla, Constance O'Hare, and Hallett H. Hammatt
  2008 Cultural Impact Assessment for the Kakaʻako Community Development District Mauka Area Plan, Waikīkī Ahupuaʻa, Honolulu (Kona) District, Oʻahu Island. TMK: [1] 2-1-29-32, 44, 46-56 and 2-3-01-11. Prepared by Cultural Surveys Hawaiʻi, Inc., Kailua

- Vogeler, Kuhio, Lehua Kauhane, and Hallet H. Hammatt
  2010 Cultural Impact Assessment for the Proposed McKinley High School Athletic Complex Master Plan Project, Honolulu (Kewalo) Ahupuaʻa, Honolulu District (Kona Moku), Island of Oʻahu. TMK: [1] 2-3-009:001 por. Prepared by Cultural Surveys Hawaiʻi, Inc., Kailua.

- Genz, Joseph H. and Hallett H. Hammatt
  2010 Cultural Impact Assessment for the Kewalo Basin Repairs Project, Kakaʻako Ahupuaʻa, Honolulu (Kona District), Oʻahu. TMK: [1] 2-1-058. Prepared by Cultural Surveys Hawaiʻi, Inc., Kailua.

- Elison, Mina and Windy K. McElroy
  2011 Final – Cultural Impact Assessment for Kakaʻako, Ahupuaʻa of Waikīkī, Kona District, Island of Oʻahu, Hawaiʻi. TMK: [1] 2-3-006:017. Prepared by Keala Pono Archaeological Consulting, LLC, Hauʻula.

In addition, two ethno-historical investigations and one Traditional Cultural Property (TCP) Study (with its Oral History – Consultation Interview Program component report) performed for areas that occur within or partially within the Kakaʻako TOD Overlay project area were reviewed, including:

- University of Hawaiʻi (UH)
  1978 *Remembering Kakaʻako: 1910-1950*. Ethnic Studies Oral History Project, Ethnic Studies Program, University of Hawaiʻi at Mānoa, Honolulu.

- McElroy, W.K., A. Sims, and M. Desilets
  2008 *Ethno-Historical Inventory Study of Kakaʻako*. Performed for Kamehameha Schools. Garcia and Associates, Kailua.

- Maly, Kepā, Onaona Pomroy Maly and Kawena Maly.
  2013 Draft He Moʻolelo ʻĀina - Traditions and Storied Places in the District Of Kona – Honolulu Region (Lands of Kalihi to Waikīkī), Island of Oʻahu. A Traditional Cultural Properties Study – Technical Report. Prepared for SRI Foundation, New Mexico.

- Elison, Mina
  2013 Oral History – Consultation Interview Program – Ahupuaʻa of Kalihi to Waikīkī, District of Kona, Island of Oʻahu. Component to Maly et al. 2013, Appendix D. A Traditional Cultural Properties Study Technical Report. Prepared by Kahiwa Cultural Heritage Consulting with Kumu Pono Associates LLC, Lanai City.

After reviewing and compiling all findings from previously conducted CIAs, ethno-historical investigations, and the Traditional Cultural Property (TCP) study (with its Oral History – Consultation Interview Program component report), protocols from the *Guidelines for Assessing Cultural Impacts* (OEQC 1997) were followed to identify cultural resources and practices not yet identified. Appendix A provides a copy of the OEQC (2013) Guidelines. The findings of these efforts are provided in this Supplemental CIA.

2.0 PROJECT AREA DESCRIPTIONS

The project area for the proposed Kaka‘ako TOD Overlay encompasses the Kaka‘ako Community Development District (KCDD) as well as Aloha Tower Special District in the *ahupua‘a* of Honolulu, Kona District, Island of O‘ahu, Hawai‘i (Figure 2). Specifically, the Kaka‘ako TOD project area consists of KCDD lands, which consist of 601.6 acres bounded by King Street to the north, Pi‘ikoi Street to the east, Ala Moana to the southeast, Māmala Bay to the south, Pier 1 to the southwest, and Punchbowl Street to the west, as well as the HECO Downtown Power Plant block comprised of 3.4 acres bounded by South Nimitz Highway to the north, Richard Street to the east, Aloha Tower Drive to the south, and Bishop Street to the west (Figure 1).

2.1 ENVIRONMENTAL BACKGROUND

Thorough environmental descriptions of the Kaka‘ako TOD Overlay project area can be found in previous CIAs performed for projects located within its boundaries (Spearing et al. 2008; Vogeler et al. 2010; Genz & Hammatt 2010; Elison and McElroy 2011).

The Kaka‘ako TOD Overlay project area is located on the leeward side of the Ko‘olau Range on the south coast of O‘ahu between Waikīkī and Honolulu. In general, environmental conditions of Kaka‘ako are relatively mild. The general geological provenience on which most of Kaka‘ako is situated is referred to as the Honolulu Plain, excluding the *makai* portions built up with fill in the Historic era. Prior to development, much of Kaka‘ako had a low marshy topography.

The area’s geomorphology is a result of volcanism attributed to the now extinct Ko‘olau Volcano, which built the island mass, followed by coastal erosion and deposition related to the Pleistocene Epoch’s glacial and inter-glacial sea level fluctuations. The coastal of Kaka‘ako consists of an elevated coralline reef that was formed during an interglacial period approximately from 120,000 to 38,000 years ago, when sea levels in Hawai‘i were some 6-8m above the present sea level, which has been termed the Waimānalo Sea Stand. During this period, coral reefs developed upwards with the gradually rising sea levels. During the next period of glaciation, sea levels dropped leaving exposed coral reefs that were then eroded by marine level fluctuation, wave/sediment abrasion, as well as weathering by rain, run-off, and wind after sea levels dropped to their present level. Further, rain water naturally absorbs carbon dioxide in the air to form a weak carbonic acid, which dissolves portions of the limestone with prolonged exposure, subsequently forming karst topography. Hallmark features of karst topography are caverns and sinkholes, which are formed as acids build up and dissolve soluble portions and natural voids in the limestone (Foote et al. 1972; MacDonald & Abbott 1970; Geolabs 2004).

Typical subsurface conditions in Kaka‘ako are a composite of Pleistocene coral and algal reef deposits mixed with terrigenous sediments or *mauka* soils (Geolabs, Inc. 2004). According to the Natural Resources Conservation Service (NCRS) Custom Soil Resource Report for the contiguous, Kaka‘ako Makai and Mauka portions of the project area are 66% mixed fill land (FL), 23.5% Makiki clay loam (MkA) with 0-2% slopes, and 4.1% Ewa silty clay loam (EmA), moderately shallow, with 0-2% slopes (NCRS 2013a). The HECO Downtown Power Plant block

is 100% mixed fill land (FL) (NCRS 2013b). Appendix B provides copies of the 2013 NCRS Custom Soil Resource Reports for the Kaka‘ako TOD Overlay contiguous and non-contiguous project areas. Fill lands consist mainly of sediment dredged from the ocean and/or hauled in from other areas of the island (Foote et al. 1972). However, Kaka‘ako Waterfront Park fill is primarily non-combustible Historic refuse (Wilson Okamoto and Associates, Inc. 2002).

The area receives less than 76 cm of precipitation annually, falling mainly between November and March. The mean air temperatures of Kaka‘ako range from lows of 15°-21°C (51°-91.4°F) to highs of 27°-28°C (80.6°-82.4F), with the coolest months being January through March and hottest from July to October (Armstrong 1983:62).

The state of the project area is fully developed and currently functions as an urban and industrial cityscape (Figure 2).

Figure 2. Current state of the Kaka‘ako TOD Overlay project area (courtesy of Google Earth).

3.0 CULTURAL LANDSCAPE SUMMARY

The land to which we now refer to as Kakaʻako has a long and rich cultural history. From Traditional Hawaiian accounts, *moʻolelo*, Historical documents, and the archaeological record it is evident that this locale has been the backdrop to many significant acts in the long drama of Oʻahu's pre- and post-Contact history. Thorough archival research was performed by Spearing et al. (2008), Vogeler et al. (2010), Hammatt and Shideler (2010), Elison and McElroy (2011), and Maly et al. (2013) to describe the cultural landscape of pre-Contact to present day Kakaʻako.

3.1 PRE-EUROPEAN CONTACT CULTURAL LANDSCAPE

Kakaʻako's current boundaries, in the Kakaʻako TOD Overlay project's configuration, appear to be a modern construct with no evidence of distinct Traditional or Historic boundaries to affirm them (Spearing et al. 2008; Vogeler et al. 2010; Elison and McElroy 2011). Rather, Kakaʻako is composed of component *inoa ʻāina* (Traditional Hawaiian localities), including Kakaʻako, Honokaʻupu, Kaʻākaukukui, Kukuluāeʻo, Kālia, Kewalo, Kou, Kuloloia, Māmala, and Pākākā, that were situated between the two major population centers, Kou (now Honolulu) and Waikīkī.

3.1.1 The Natural World

The mundane, or lifeways and land use, of pre-European contact Hawaiians are integral components of the cultural landscape and are interpreted through archaeological research in conjunction with oral histories and recorded traditional accounts. Handy and Handy (1991) provide some commentary on general land use patterns of ancient Hawaiians that are applicable to the general Kakaʻako area. As marine resources represent the main source of protein in the traditional Hawaiian diet, Handy and Handy (ibid.) suggest that upland agriculture was typically preceded by or correlated with the productiveness of an area's coastal fishing grounds. *Mauka* lands were intensively developed in areas where coastal fishing grounds were easily accessed. On Oʻahu, sweet potatoes were cultivated to supplement taro, the main starch of the Hawaiian diet, when soils were too sandy or dry to grow taro. Further, sweet potato cultivation, typically grown inland, appeared to correlate with high population densities in general.

Traditionally in Hawaiʻi, environmental zones were perceived and determined by various natural features and resource criteria (Handy and Handy 1991:54-56). The following describes the general terrestrial environmental zones:

1. *Ko Kaha Kai*: Land by the sea, or coastal region providing marine resources (fish and other marine animals, seaweed and salt). "Kaha was a special term applied to areas facing the shore but not favorable for planting."
2. *Kula*: The plains or sloping lands (without trees) above the coastal region.
    a) *Kula kai*: Seaward plains.
    b) *Kula uka*: Inland or upland slopes (towards the mountains).
3. *Kahawai*: The place (having) water. The area beyond or intersecting the *kula* lands. This upland zone provided suitable agricultural sites and abundant naturally occurring resources which were used for religious, domestic, and economic purposes.
4. *Wao*: Wilderness
    a) *Wao kanaka*: Region of man. Lower forest, providing hard wood (*koa*) for spears, utensils, and logs for canoes; *lau hala* (pandanus leaves) for thatch and mats; *māmaki* for bark cloth (tapa); *kukui* (candlenut) for oil; wild yams, roots, and sandalwood.
    b) *Wao akua*: Region of deities. …remote, awesome, seldom penetrated, source of supernatural influences, both evil and beneficent.
    c) *Wao maʻukele*: Rain forest. Here grew giant trees and tree ferns (*ʻamaʻu*) under almost perpetual cloud and rain.

The lands now known as Kakaʻako are located in the environmental zones of *Ko Kaha Kai* and *Kula Kai*.

Traditionally in ancient Hawaiian culture, marine zones were also distinguished by various natural features and resource criteria. The following describes the marine environmental zones (Handy and Handy 1991:56-57):

1. Neritic zone: Near-shore waters, extending from the upper reaches of the tidal edge to about 200m in depth. Contains the most resources for human use. (Midden remains from Hawaiian sites show a preponderance of species from neritic habitats [Clark 1986:34]). Corresponding to the Hawaiian marine habitats of:
    a) *Kai puʻe one*: (heaps [of] sand) the sandy edge of the sea, inshore dunes, or outer sand bar;
    b) *Kai poʻi*: (sea-breaking) out to where the wave breaks;
    c) *Kai kohola*: the lagoon, the shallow sea inside the reef;
    d) *Kai pualena*: the yellowish sea, where the streams flow in and roil the waters;
    e) *Kai ʻele*: the dark sea; and
    f) *Kai uli*: the deep blue-sea.

2. Pelagic zone: the open ocean, waters lying beyond or exceeding the depth of 200 meters.
    a) *Kai-pōpolohua-mea-a-Kāne*: the far reaches of the open sea

Marine environments were subject to the traditional resource management system as well, supported by the *kapu* (religious law) system in ancient Hawaiʻi, which preserved *lōkahi* (balance) on many levels between humans and these resources. Various marine resources were key to pre-Contact era Hawaiian life. *Iʻa* (fish), *he iʻa mea iwi mawaho* (shellfish), *heʻe* (octopus), *limu* (seaweed), *paʻakai* (salt), *ʻākoʻakoʻa* (coral), *pōhaku* (stones), *manu* (bird), and *honu* (turtle). These resources were used for sustenance, tool making, medicine, trade, architecture, and ceremony. *Paʻakai* was one of the most important marine resource for its many applications, including food preservation, seasoning, medicine, and ceremonial use (Brigham 1908; Westervelt 1915; Malo 1951:132).

3.1.2 Traditional Hawaiian Land Divisions

The pre-Contact economy of the Hawaiian Islands was based upon agricultural production that worked within a tiered system of land divisions (Lyons 1875; Malo 1951; Handy and Handy 1991; Kirch 1985; AKAC 2010). In 1875, Curtis J. Lyons, the distinguished surveyor published an article in *The Islander* on land issues, which identified the *ahupuaʻa* as the principal subdivision in a *moku*. In this article, he states:

> ...Its name is derived from the *Ahu* or altar; (literally, pile, *kuahu* being the specific term for altar) which was erected at the point where the boundary of the land was intersected by the main road, *alaloa,* which circumferenced each of the islands. Upon this altar at the annual progress of the *akua makahiki* (year god) was deposited the tax paid by the land whose boundary it marked, and also an image of a hog, *puaa,* carved out of kukui wood and stained with red ochre. How long this was left on the altar, I do not know, but from this came the name, *ahupuaʻa,* of the pile of stones, which title was also given to the division of land marked thereby… (Lyons 1875:103-104).

The islands are divided into several sections called *moku* (districts), in which are particular subdivisions referred to as *ʻokana* (a portion) or *kalana* (a division) (Lyons 1868:67-68; Malo 1951:16-17). According to Curtis J. Lyons (1868) in *Nūpepa Kuakoa*, these units are further divided into *ahupuaʻa*, which are the main units of traditional Hawaiian land division. Within *ahupuaʻa* are *ʻili*, followed by *ʻili paʻa, ʻili kūpono, ʻili lele, lele, moʻo, moʻo ʻāina, paukū, kīhāpai, kōʻele,* and *kuleana* (Pukui and Elbert 1986). However, in some cases, the *ʻili kūpono* or *kū* were a type of sovereign *ʻili* within an *ahupuaʻa* that were not made to pay tribute to the chief (Thrum 1890:106). Within the *paukū* are dry land patches, referred to as *kōʻele*, *hakuone*, and *kuakua* (cultivated specifically for the chief; listed from smallest to largest). In general, high elevations or mountains are called *mauna*, but mountains or mountain summits located centrally on the island are termed *kuahiwi*, while the peaks or ridges on top of the *kuahiwi* are called *kualono*. In 1868, Lyons continues to describe the geography of the typical *ahupuaʻa* as well as the Hawaiian names for these geological features, stating:

> The place where trees are small below the fern belt is termed kuahea (hillock section); below it is the wao (wild place), also called waonahele (wilderness) and wao eiwa (ninth wilderness). The place where trees grew taller below the wao eiwa is the wao maukele, and a little below it again is the waoakua (spirit region); next below that is where voices increase and, hence, called wao kanaka (people's sphere), because there the people cultivate food. Below that is apaa, and next is ilima (where this plant of the Sida genus is found), and below it is pahu (stake or land mark). Below pahu is kula (open country) adjoining habitations, and seaward of the village is the shore, where it joins the sea. Such was the island divisions by the ancient people of Hawaii.
>
> …Places that stand high up in this and that locality are called puu (mounds or peaks) ; if they stand in a row they are a lalani puu, or pae puu (a line or range of peaks or hills)…High places of the earth lying narrow is a lapa (ridge), or kua lapa (shoulder ridge). If the ridges are many they are called olapalapa (rough protuberances). Deep places lying lengthwise are called kahawai, awawa, or owawa (streams, valleys or ditches). Lengthy, solitary places are called alanui (roads), and kuamoo (paths), and if it continues circuiting the island it is a highway. In places where the path is steep it is called piina or hoopiina (ascending path), kooku (hill slope), and auku (up hill road). Descending paths are termed ihona, alu, kalua, and hooihona, and the place where men would rest is oioina (a resting place). Places where water flows continually are streams (kahawai). Inland places are kumu (source) and seaward places are called nuku (point or outlet). Where water is led to places of cultivation, that is called an auwai (watercourse) ; where the water joins the sea is a muliwai (river) ; waters borne within the land are lokos (lakes or ponds) (C.J. Lyons 1868 as cited in Thrum 1921:67-68).

Perhaps the ancient Hawaiians created names for an array of topographical features and slight variations within the *ahupuaʻa* as a way to help keep the dynamic *mauka-makai* economic structure organized.

With great variations of geological features, each *ahupuaʻa* had its own dynamic resource management system that was based on traditional customs upheld by the *kapu* system, or ancient religious law. The *ahupuaʻa* typically extended form the coast to the nearest mountain top or ridge and resources from the land and sea were equally distributed within the *ahupuaʻa*. Lyons (1875) describes the geographic nature of the *ahupuaʻa* as well as the movement of resources from mountain to sea and vice versa, stating:

> The Ahupuaa ran from the sea to the mountain, theoretically. That is to say the central idea of the Hawaiian division of land was emphatically central, or rather radial. Hawaiian life vibrated from *uka,* mountain, whence came wood, kapa, for clothing, olona, for fish line, ti-leaf for wrapping paper, *ie* for rattan lashing, wild birds for food, to the *kai,* sea, whence came *ia,* fish, and all connected therewith. Mauka and makai therefore fundamental ideas to the native of an island (Lyons 1875: 104).

The *ahupuaʻa* was also an important socio-political unit in the pre-Contact era, each unit with its own hierarchy. Kirch (1985) holds that *moku* were independent chiefdoms, divided into a number of radial land divisions, referred to as *ahupuaʻa,* with subdivisions of *ʻili* and *moʻo* within. According to Kirch (1985),

> Each ahupuaʻa was controlled by a lesser chief, who in turn appointed one or more stewards to oversee production, organize work parties, collect tribute, and in other ways represent the chief. Ahupuaʻa were economically self-sufficient to some degree, although differences in the local resource base (agricultural land, water resources, stone for tools, and so on) resulted in differences in the production patterns of individual land sections. Within the ahupuaʻa, there were yet smaller sections and divisions, especially the ʻili and moʻo, which were held and worked by extended households or groups of commoners (Kirch 1985:2).

According to Handy and Handy (1991), for the purpose of taxation, the chief political subdivision of the pre-Contact era was the *ahupuaʻa,* which was generally under the management of the *konohiki* (steward or caretaker). The term *ahupuaʻa* itself is derived from the fact that each coastal *ahupuaʻa* boundary was marked with an altar (*ahu*) which held a carved

wooden effigy of a pig (*pua'a*) head during the Makahiki festival, when harvest tributes (taxes) were offered to the god of rain. Handy and Handy (1991) refer to the lower chief who represented the *ahupua'a as ali'i 'ai ahupua'a,* which translates to English as "chief who eats the ahupua'a" (1991:48). Yet, according to Malo (1951:142) the *konohiki* was tasked with collecting levies from the *maka'āinana* (commoners; literally "people that attend the land") of the *ahupua'a* for the king and of the *ali'i 'ai ahupua'a.* The word *konohiki* is defined by Pukui and Elbert as the, "Headman of an ahupua'a land division under the chief; land or fishing rights under control of the konohiki; such rights are sometimes called konohiki rights" (Pukui and Elbert 1986:166). Thrum wrote that the *konohiki* was a local representative or steward of the landlord owner whose privileges and duties were, "…practically those which go with that position in any land and in common with his brethren today in Russia or Ireland he had his failings and was not always popular among his fellows…" (Thrum 1924:60).

Handy and Handy liken the *ahupua'a* tenure system to western share cropping, where "sharing between the chief and tenant was comprehensive and reciprocal in benefits" (Thrum 1991:48). Kirch and Sahlins (1992:17) delve further into the social dynamics of the *ahupua'a* in their historical ethnography, *Anahulu: The Anthropology of History in the Kingdom of Hawaii, Volume One*. Kirch and Sahlins state the following about variations in land use in the ancient *ahupua'a*:

> Economically more highly valued, the coastal areas were also generally preferred for chiefly residence. Here were the most extensive wet taro lands, offshore and onshore fish ponds, as well as access to the sea and the fishing and surfing that in Hawaii were sports of kings. Still, the uplands were also necessary for the Hawaiian existence. In addition, to things mentioned by Lyons, people were specifically dependent on the uplands for the timber and thatching of their houses; the materials for their canoes, bowls, weapons, images, agricultural tools, and other objects using hardwoods; rope, line, fishnetting; lighting (form candlenuts); pasture for domestic animals (in the nineteenth century); various fruit trees; and more (Kirch and Sahlins 1992:19).

Thus, resources needed for daily life were best grown in or collected from the habitats that they were best suited for and likely distributed, through trade, gifting, or taxes, from *mauka* to *makai* or vice versa within the *ahupua'a*.

The original configuration of Kaka'ako's traditional boundaries is unclear, though the area that is widely held as Kaka'ako appears to have grown and morphed significantly since the early European Contact period. Spearing et al. (2008:12) cite the ethnographer and long-time resident of O'ahu, Henry Kekahuna (1958:4), who placed the boundary for Kaka'ako "on the Ewa side of Kuloloia Stream where the Honolulu Iron Works and Fort Armstrong are now," an area now covered by One Waterfront Plaza (between South and Punchbowl Streets). Further, Historic maps (Bishop 1884; Monsarrat 1897; Lyons 1872) show Kaka'ako in a variety of configurations if they show the locality at all. Mid 19th century documents and maps describe Kaka'ako as a small *'ili* located in the *ahupua'a* of Honolulu (Spearing et al 2008:12).

3.1.3 *Inoa 'āina* (Hawaiian Names for Localities) & *Wahi Pana* (Storied Places)

The area now referred to as Kaka'ako has a long and colorful past. Many *inoa 'āina* within Kaka'ako were derived from legendary people and events. Some locations have been the back

drop of *mo'olelo* and are, thus, *wahi pana*. In the modern era, these *inoa 'āina* and *wahi pana* are not always used as place names for the areas that they once described. Westervelt (1915) offers very comprehensive explanations for these ancient place names in *Legendary Places in Honolulu* as does Spearing et al. (2008) and Maly et al. (2013). Figure 3 is a map of the approximate locations of *inoa 'āina* and *wahi pana* in Kaka'ako, which is based upon written descriptions and maps created by The SRI Foundation (2013:Appendix E-1 through E-4).

'Āina Hou
The land stretching from Pākākā to Kaka'ako (lower Fort Street to Kewalo Basin) on the east side of the harbor was referred to as 'Āina Hou, according to Kamakau (1961:419).

'Āpua
The place name translates as "woven fish basket," which is shared with its namesake who was a fisherman from the area between Richards, Queen, and Punchbowl Streets (Maly et al. 2013). This location is mentioned in Thrum's (1900) version of the legend of Kū'ula as an area that his son, Aiai stayed while on his journey in O'ahu and was the home of his companion Apua, who shares the name.

'Auwaiolimu
The name 'Auwaiolimu translates as "water channel of algae or mossy stream" and was the name of the area between the coastal lands of Waikahalulu and Honuakaha, which is now near Hale Kauwila and Queen streets (Maly et al. 2013).

Awalua
Ancient surf break, also called Kaawalua located in the Māmala Channel (Ī'ī 1959:82).

Hale Kauwila
Hale Kauwila, which means "house made of *kauwila* wood," is a Historic era name of the area that connects Pākākā and the old Fort. The name actually referred to one of the large thatched structures near the shore of Kuloloia, which was built for the *ali'i* Maly et al. (2013). Hale Kauwila is the location where the King and his officials met and made decisions for the Hawaiian Government.

Hale o Lono
According to Ī'ī (1959), Hale o Lono was a *heiau* that at one point had been the residence of Liholiho (Kamehameha II). Maly et al. (2013:30) states that Hale o Lono once stood near the corner of Fort and Queen Streets.

Honoka'upu
The ancient locality of Honoka'upu, which means "Albatross Bay," is named after Chief Honoka'upu. It is mentioned in Ī'ī (1959:91), where he describes it as a bathing pool or spring located "…above Queen Street, north of a pier at the corner where Queen and Alakea Streets now meet..." and states that this property, belonging to Kaiwikokoole, was located near to King Kamehameha's son, Kekuaiwa. To the east of Kou was a bond surrounded by a grove of coconut trees that was named after Chief Honoka'upu (Westervelt 1915). Ī'ī (1991:161) later writes that Honoka'upu is Kekauluohi's coral stone house located at Pohukaina, which is said

by Pukui et al. (1974:187) to have been located behind the Hawai'i State Library. The *Saturday Press Dictionary of Hawaiian Localities* (September 22, 1883:5), stating "Honokaupu Land in Honolulu on Queen Street, and between Fort and Alakea Street" (as cited by Maly et al. 2013:51). Westervelt (1915:4) holds that Honoka'upu was noted as a court for playing *ulu maika.* Further, the *mele* for Chiefess Mamala, who was the wife of Chief Honoka'upu, mentions Honoka'upu as being the location of a small *kōnane* board (Westervelt 1915:52-54). Maly et al. (2013:108) describes Honoka'upu as a being a trail junction as well.

Honolulu

Honolulu, which means "calm/peaceful cove" is the location once referred to as Kou (Maly et al. 2013) is the name of the *ahupua'a* that contains much of Kaka'ako. Westervelt (1915) offers a description of the original location of Honolulu:

> "Honolulu" was probably a name given to a very rich district of farm land near what is now known as the junction of Liliha and School Streets, because its chief was Honolulu one of the high chiefs of the time of Kakuhihewa according to the legends. Kamakau, the Hawaiian historian, describes this farm district thus "Honolulu was a small district, a pleasant land looking toward the west, - a fat land, with flowing streams and springs of water, abundant water for taro patches. Mists resting inland breathed softly on the flowers of the hala tree."
>
> Kakuhihewa was a king of Oahu in the long, long ago, and was so noted that for centuries the island Oahu has been named after him "The Oahu of Kakuhihewa." He divided the island among his favorite chiefs and officers, who gave their names to the places received by them from the king. Thus what is now known as Honolulu was until the time of Kamehameha I., about the year 1800, almost always mentioned as "Kou," after the chief Kou who was an "Ilamuku," or "Marshal," under the king Kakuhihewa. "Kou" appears to have been a small district, or, rather, a chief's group of houses and grounds, loosely defined as lying between Hotel Street and the sea and between Nuuanu Avenue and Alakea Street (Westervelt 1915:1-2).

Kamakau (1961) mentions the place name of "Honolulu" as being used during the time of Alapa'i:

> Then Alapa'i determined to sail to Oahu and take possession of that island; for he had heard that it was without a ruling chief, Pele-io-holani being at that time ruling chief of Kauai. Alapa'i therefore sailed to Oahu with his chiefs and fighting men, accompanied by the chiefs of Molokai. Inquiring about the harbors on Oahu, he was told by those skilled in such things that, "Waikiki has a harbor, Wai'alae has a harbor; these are both good harbors; at Waikiki and Honolulu live most of the chiefs" (Kamakau 1961:71).

This statement of Alapa'i also mentions that most of O'ahu's chiefs dwelt in Honolulu. Further, Kamakau (1961:82) refers to the war between Kahekili and Kahahana in 1782 as the "battle of Honolulu." He later writes of Kou as being a harbor of Honolulu in the early Contact period, stating: "But during the early days of the war a couple of foreign ships entered the harbor of Kou at Honolulu, the first to enter that harbor" (Kamakau 1961:168).

Honuakaha

Honuakaha, which means "marked earth or coastal land," is an area bound by Queen and Punchbowl Streets (Maly et al. 2013). Although, Thrum (1922:633) translates it as "flat land." This area was the location of a royal coconut grove and the former residence of Chief Kinau, father of Miriam Kekauonohi. Spearing et al. (2008) cites a legal suit over a *lele* of the Ili of Kaalaa at Honuakaha that consisted of 1.6 acres that were formerly fishpond and dry land (Hawaii Reports 1903:321, 324 as cited by Spearing et al. 2008:40).

Ho'okūkū

The area referred to as Ho'okūkū, which was between Honuakaha and Honoka'upu, is where a healing heiau and home of Liholiho once stood. Queen Street now runs through the area (Maly et al. (2013).

Hu'ehu'e

The name translates as "overflowing" and represents an area that is bounded by Queen Street and Honoka'upu (Maly et al. 2013).

Ka'ākaukukui

Ka'ākaukukui was once a reef that has been covered with fill. The name translates as "the right (or north) light," referring to a navigation landmark for seafarers (Spearing et al. 2008). Kekahuna (1958:4) states that Ka'ākaukukui was "a beautiful sand beach and reef that formerly extended a quarter mile along Ala Moana Park to Kewalo Basin. Other translations of Ka'ākaukukui consist of "radiating place for lamp" (Thrum 1922:635) and "to the right of the lighthouse" (Gessler 1937:187), as the 1869 Honolulu Lighthouse, no longer standing, was east of this location. Ka'ākaukukui was a "jump land" or *lele*, which is a non-contiguous portion of land belonging to an *'ili*. One lot of the *lele* was located on the coast and the other two were inland (Spearing et al. 2008:15-16).

Maly et al. (2013:32) translates Ka'ākaukukui as "The north/right light," and describes it as a coastal land "east of Waikahahulu, and adjoining Kukulu'āe'o." Further, Maly et al. (2013:32) holds that the area, once fronted by fishponds and salt works, was cited in historical accounts, Māhele Claims 6236, 7712, 7713 and 10605, and Register Map numbers 241, 395, 611, 861, 900, 1090, and 1471.

Spearing et al. (2008) found that Ka'ākaukukui was briefly mentioned in the Hi'iaka legends, where Hi'iaka and her companions decided to travel from Pu'uloa (Pearl Harbor) to Waikīkī by canoe after traveling around O'ahu by trail. While in Pu'uloa, Hi'iaka met a party who were en route to visit the chiefess Pele'ula in Waikīkī by land trail. Hi'iaka informed people that she would travel by sea and meet them in Kou. The chant Hi'iaka recited is as follows:

And what of me, O Honoka'upu, my love	*A pehea lāau, e Honoka'upu, ku'u aloha*
Upon the crest of the surf at Uhi and 'Oā	*I ka welelau nalu kai o Uhi, o 'Ōa*
Eyes in the living realm (night) of oblivion	*'O nā makai ke ao (pō) o poina*
Where am I, O my love	*Ma hea lā wau, e ke aloha lā*
Kou is the coral flat	*'O Kou ka papa*

Kaʻākaukukui is the pool	*ʻO Kaʻākaukukui ka loko*
Some ʻalamihi indeed	*ʻO ka ʻalamihi aʻe nō*
Wait all day until night	*ʻO ka lā pō iho*
Friends shall meet in Kou.	*Hui aku i Kou nā maka.*

(Hoʻoulumāhiehie 2006a:277; Hoʻoulumāhiehie 2006b:297)

Kaheiki

Kaheki, which means "little flow," is described as a *heiau* of *poʻokanaka* (human sacrifice) class, according to Maly et al. (2013:33) as well as the name of a land area and stream, however, the location is only noted as Honolulu. In "The Career of Boki," Kamakau (1961) describes a large boulder in Kaheiki Stream named Hōʻeu, which was the guardian of Keheiki:

> Boki started to work at the makai road leading to Kaʻalaʻa and when he reached the stream of Kaheiki there stood a great rock over the stream blocking the way. Boki was trying to remove it when a man came forward and said, "Hear, O chief! leave that rock alone. The god made this rock a guardian for this place and his house is yonder (pointing upward to Kaheiki). It is a guardian for the house of the god and its name is Hoʻeu. The nature of this rock is that if you move it aside it will make you move to a foreign land and you will no longer live in Hawaii. Lucky for you if a year passes before you depart." Boki's pipe lighters, Hohopa and Hukiki, reproved the man, to whom he answered, "Take care lest you be thrown onto a bed of thistles!" While working on the Luakaha road Boki found a long, pointed rock in his way and was starting to remove it when a divining kahuna named Luʻau who was skilled in pointing out locations came forward and said to him, "Do not disturb this rock; it is named Ku-of-exceeding-great-mana (Ku-manamana) and Rock-of-exceeding-great-mana (Pohaku-manamana). Not even a high chief should disturb that rock, for it covers the waters of Ka-papa-i-kawa-luna which lie below it and supply the waters of Kunawai, Kahoa-kane, Koʻula, and Kewalo." Boki instantly ordered the men to remove the rock, but it extended into the soil so far that when they had dug some ten fathoms down and about the same distance either way, he gave up in despair. Luʻau also showed him Kukui-puka and other kupua objects mauka of this place (Kamakau 1961:292).

In addition, Kamakau (1961:136) tells of a battle between Kahekili and Kahahana in 1783 that was fought at Kaheiki, where the "waters of the stream of Kahe-iki ran red with blood from the heaps of broken corpses that fell into the water; the stream was dammed back with the corpses of those who died in battle."

Kaholoakeāhole

The translation of Kaholoakeāhole is "the running/schooling of the āhole fish," according to Maly et al. (2013:33) and is the "point along the shoreline below Kākāʻako, near where fishermen resided in the time of Kamehameha I."

Kahuananaula

According to Maly et al. (2013:33), Kahuananaula is the traditional place name of the area "situated between King and Merchant Streets, and bounded between Fort and Alakea Streets."

Kaimukanaka or Umukanaka

Kaimukanaka translates as "the human oven" and is the name of an area and pond in Kaʻākaukukui (Spearing et al. 2008; Maly et al. 2013). The pond is said to be referred to as Kaimukanaka, Umukanaka, or Ka-imu-hai kanaka, all of which appear to be associated with human sacrifice.

Kakaʻako

Kakaʻako, which means "to strike and gather," is described as a land area situated between Honuakaha and Kaholoakeāhole that contained a fishing village in the pre-Contact era (Maly et al. 2013). There is no meaning given for the place name Kakaʻako in *Place Names of Hawaiʻi* (Pukui et al. 1974). However, Pukui and Elbert (1986:110) provide a translation for the word *kākāʻāko* as "dull, slow." Alternatively, Thrum (1922:639) suggests *kākāʻāko* means to "prepare the thatching," based on the meaning of the name's first half, *kākā*, "to chop, beat, or thresh" and its last half, *ako,* which means "thatch." Spearing et al. (2008) speculate that the name could tie into the fact that tall *pili* grass, used to thatch traditional structures, thrived in salt marshes, such as those in Kakaʻako - provided that Thrum's translation is correct.

In Thrum's (1900:123-128) version of the legend of Kūʻula, Kakaʻako is mentioned as the location that Aiai, son of Kūʻula, stayed for several days and was befriended by a local named Apua.

Kālia

The name Kālia translates as "waited for," and is a coastal *ʻili* of Waikīkī Ahupuaʻa, once famous for its salt production and fishponds (Maly et al. 2013). This location was also mentioned in Thrum's (1900) version of the legend of Kūʻula as the location where Aiai first came to on the island of Oʻahu from Molokaʻi.

Several proverbs were found regarding Kālia:

> *He kai hului ko Kālia.*
> A sea for fishing with a drawnet is the sea of Kālia.
> (Pukui 1983:71)

This proverb suggests, according to Pukui (1983:71) that the water at Kālia is very shallow.

> *Ke kai wawalo leo leʻa o Kālia.*
> The pleasing, echoing sea of Kālia.

Pukui (1083) places the sea of Kālia as the current location of Ala Moana (Pukui 1983:186).

Kaʻoaʻopa

According to Maly et al. (2013:36), Kaʻoaʻopa is a section of coastal land situated between Mokuʻaikaua and Honuakaha. The trail from Kou to Waikīkī ran through this location. Kaʻoaʻopa is also the location where the attendants of Kamehameha II (Liholiho) lived during the reign of Kamehameha I (Maly et al. 2013).

Kauanonoʻula

Roughly located at the intersection of Merchant and Alakea Streets, Kauanonoʻula is said to have been a regular haunt for ghosts. Westervelt (1915:4) holds that Kauanonoʻula, or "rain with the red rainbow," was a place where *wailua* (ghosts) were known to gather "for nightly games and sports." . Kamakau (1961) holds that Kauanonoʻula is named for an ancient chiefess, and wife of Honokaʻupu. Kauanonoʻula, translated by Maly et al. (2013:128) as "the red glowing rain" and provides a background story for the name from an article in the *Nūpepa Kuokoa*, "*Kuu Kamaaina i ka ua Kukala Hale*" (January 24, 1919:3). The story is as follows:

> It is because of a beautiful chiefess that this place is named Kauanonoʻula. It was there that she and her family resided. This is the chiefess who took Honokaʻupu as her chiefly husband, and it was at this place that they played their favorite game of kōnane. This is why the famous saying came about, "Huhuhui aku nā maka i Kou" (The eyes will meet at Kou) and "Hāhā pōele ka pāpaʻi o Honolulu" (The crabs of Honolulu grope about in the dark).
>
> Here is the tradition: It is said that the kōnane playing area of the chiefs was there by Fort Street, close to Queen Street, where the bank of Spreckles is; and at this place many people, attractive men and women, gathered for these pleasurable kōnane games of the chiefs.
>
> The kōnane board of this story was made from a large kou tree that was taken from a place nearby what is now Kapiolani Park in Waikīkī. And on the board, were marked lines and four corners in which the various pieces were set.
>
> It was in those days that the name, Kou was given to that place, because of the pastime of the chiefs, and the murmuring voices of the sweethearts could be heard about, "Huhuhui aku na makai Kou," that is the saying was spoken there [sic], inviting the desire of those who were entwined in the embrace of love to meet. Auwe!
>
> As night set out its cover, the men and women would begin to ask and seek out their companions and the saying was uttered "Hāhā pōele ka pāpaʻi o Honolulu," [sic] Thus the night was not without the groping hands - So that which was seen is finished (translated by Maly et al. 2013:128).

This story describes the general tone of this location during *kōnane* games as being a party-like atmosphere.

Kawaiahaʻo

The area in which Kawaiahaʻo Church is located was once the location of a fresh water spring that belonged to a chief named Hao, hence the name Kawaiahaʻo, which translates to English as "The water belonging to Hao," according to Westervelt (1915:3). Pukui et al. (1974) describes Kawaiahaʻo as an *ili* land once noted for its spring and healing waters. Haʻo is mentioned as both a chief and chiefess in accounts for the area (Maly et al. 2013). Kawaiahaʻo is cited in traditional and historical accounts; Māhele Claim 10605, and Register Map No.'s 111 and 900, and 1912 map by Baldwin & Alexander (SRI Foundation 2013:B-8).

Pukui (1988) recaps a *mo olelo* of the Waters of Haʻo, which describes two springs in Kewalo. In this story, two of chief Haʻo's children ran away from their malicious stepmother and hid for a time at Kewalo Spring. This spring is thought to have been near the trail that connected Waikīkī and Kou. When the children heard that the chiefess had sent men to look for them, the children took the trail across the plain to Kou that night, but succumbed to exhaustion and dehydration. At the western end of the trail, near Kawaiahaʻo Church in Kakaʻako is where the children stopped to rest. One of the children had a dream while he slept, where the boy's mother told him to pull up a plant near his feet. After pulling up the plant, a spring was found. This spring came to be known as the Water of Haʻo, or Kawaiahaʻo, after the children's father (Pukui 1988:87-89).

Ke-kai-o-Mamala

Ke-kai-o-Mamala was the name of a surf break at the outer entrance of the harbor of Kou, which was named after the chiefess Mamala. Westervelt (1915:2) describes the chiefess as a remarkable woman "who loved to play konane Hawaiian checkers drink awa and ride the surf."

Kekaukukui

Several Historic maps exhibit a location referred to as Kekaukukui, which is said to have been close to Ulakua (Westervelt 1915:4). Kekaukukui was reportedly a hub for *kōnane* (a type of pebble board game). Westervelt (1915:4) states:

> Kekaukukui was the place where small konane (checker) boards were laid. These were flat stones with rows of little holes in which a game was played with black and white stones. Here Mamala and Ouha drank awa and played konane (Westervelt 1915:4).

Westervelt (1915:4) also holds that Kamehameha V's father, Kekuanaoa, built his home at Kekaukukui.

Kewalo

Kewalo, which is translated as "the calling," represented a vast *kula* and coastal region, but is now a name that refers to a manmade basin on the coastline of Kakaʻako. Westervelt (1915) provides a glimpse of ancient Hawaiian practices that took place in this area, stating:

> Kewalo was the place where the Kauwa, a very low class of servants, were drowned by holding their heads under water, according to the law known as "Ke-kai-he-hee." "Kai" means "sea" and "hee" means "surf-riding" or "sliding along." The law meant the sliding of the servants under the waves of the sea (Westervelt 1915:3).

He also holds that Kewalo is the nesting place of the owl responsible for initiating the great battle between the legendary owls who gathered from Hawaiʻi to Kauaʻi and chief Kakuhihewa's army. In this story, the protagonist, Kapoʻi, came across pueo eggs as he was gathering pili grass on the slopes of Punchbowl. Kapoʻi collected the eggs for his dinner, but the owl pleaded for Kapoʻi to return the eggs. After the pueo shamed the protagonist and correctly answered the correct number of eggs he found, Kapoʻi gave in to the pueo and returned the eggs. His acquiescence and return of the eggs reflects his acceptance of the owl as

his *'aumākua*." As Kapoʻi was beholden to the owl, he was commanded to erect a *heiau*, make it *kapu* (sacred), and perform rites there. These actions were strictly prohibited by the ruling chief of Oʻahu, Kekuhihewa. Upon hearing the actions that Kapoʻi took, Kekuhihewa ordered the lawbreaker to be captured and killed upon Kūpalaha Heiau. However, the pueo then amassed an army of owls who successfully freed Kapoʻi from his gruesome fate at Kūpalaha Heiau (Westervelt 1915: 135-137). Kukaeunahiokapueo, which means "the confused noise of owls rising in masses," is the traditional place name of the great battle of the owls (Spearing et al. 2008).

In the legend of Pumaia, Kewalo was the location of a battle in which Pumaia killed all of Kualiiʻs warriors and officers (Fornander 1917:492).

Hua-nui-ka-lā-laʻilaʻi, one of Oʻahuʻs distinguished chiefs, was born at Kewalo. The following *mele* recorded by Kamakau (1991) describes this event:

ʻO Hua-a-Kamapau ke ʻliʻi	Hua-a-Kamapau the chief
O Honolulu o Waikīkī	O Honolulu, of Waikīkī
I hanau no la i kahua la i Kewalo,	Was born at Kewalo,
ʻO Kālia la kahua	Kālia was the place [the site]
O Makiki la ke ēwe,	At Makiki the placenta,
I Kānelāʻau i Kahehuna ke piko,	At Kānelāʻau at Kahehuna the navel cord,
I Kalo i Pauoa ka ʻaʻa;	At Kalo at Pauoa the caul;
I uka i Kahoʻiwai i	Upland at Kahoʻiwai, at
Kanaloahoʻokau . . .	Kanaloahoʻokau. . .

(Kamakau 1991:24)

Kolowalu

Kolowalu, which encompassed a large fishpond, is located within Kukuluāeʻo and abutted the lands of Kālia and Kewalo. Kolowalu is an ancient benevolent law that existed during the reign of Kualii, which is explained by Fornander (1917) as:

> It was strict, unvarying and always just. It was for the care and presentation of life; it was for the aged men and women to lie down in the road with safety; it was to help the husbandmen and the fishermen; to entertain (morally) strangers, and feed the hungry with food. If a man says, "I am hungry for food," feed [him] with food, lest he hungers and claims his rights by swearing the kolowalu law by his mouth, whereby that food becomes free, so that the owner thereof cannot withhold it; it is forfeited by law. It is better to compensate. He who swears must observe the law faithfully, lest he be accountable to the law of the king which he has sworn to observe, and the punishment be upon him. If it is simple robbery of others' food, or of others' property, then severe punishment shall be meted out to the person who violated the law. A transgressor, or one who is about to die, is, under the application of this law exonerated of his death or other penalty. Through the uprightness of his [Kualii's] law, and the honesty with which he administered the government, God preserved him, so that he lived a long life, and his is that notable life spoken of in the annals of the ancient people, of the king of Oahu, who lived four times forty and fifteen years. In the last stage of life he was bent with age and withered, with the eyes reddened and bedimmed; and

> was carried about in a netting. He died at Kailua, in Koolaupoko, in A.D. 1730, in the one hundred and seventy-fifth year of his life (Fornander 1917:432).

Kou

The area now referred to as Honolulu (lit. Sheltered or Protected Cove) was traditionally referred to as Kou, due to the fact that *kou* tree groves were prominent features in its landscape. According to Kamakau (1976), Honolulu as the name of a locality originally referred to a *loʻi kalo* (taro patch) located at what is now the intersection of Liliha and School Streets, which bore the name of its caretaker, Honolulu. Because Honolulu was so well loved, Kamakau states that "his descendents gave this name to the whole ahupuaʻa" (1976:7). Westervelt (1915:1) holds that there are various translations for the place name of Honolulu, including "Sheltered Hollow" and "abundance of peace." He further states:

> "Honolulu" was probably a name given to a very rich district of farm land near what is now known as the junction of Liliha and School Streets, because its chief was Honolulu, one of the high chiefs of the time of Kakuhihewa, according to the legends. Kamakau, the Hawaiian historian, describes this farm district thus: "Honolulu was a small district, a pleasant land looking toward the west, — a fat land, with flowing streams and springs of water, abundant water for taro patches. Mists resting inland breathed softly on the flowers of the hala- tree."
>
> Kakuhihewa was a king of Oahu in the long, long ago, and was so noted that for centuries the island Oahu has been named after him "The Oahu of Kakuhihewa." He divided the island among his favorite chiefs and officers, who gave their names to the places received by them from the king. Thus what is now known as Honolulu was until the time of Kamehameha I., about the year 1800, almost always mentioned as "Kou," after the chief Kou, who was an "Ilamuku," or "Marshal," under the king Kakuhihewa. "Kou" appears to have been a small district, or, rather, a chief's group of houses and grounds, loosely denned as lying between Hotel Street and the sea and between Nuuanu Avenue and Alakea Street (Westervelt 1915:1-2).

Westervelt (1915:8) also states that Kou was likely the most prominent place on Oʻahu to play *kōnane*, which is an ancient board game played with pebbles. He describes the *kōnane* hub as being located near to the temple; likely Pākākā Heiau. This is upheld in a proverb from Pukuiʻs *ʻŌlelo Noʻeau*:

> *Hāhā pōʻele ka pāpaʻi o Kou.*
> The crabs of Kou are groped for in the dark.
> (Pukui 1983:50-51)

This proverb refers to one who "goes groping in the dark," but alludes to the days in which the chiefs of Kou held *kōnane* games at the shoreline of Kou, which often lasted into the night, causing the spectators to "grope for their companions" (Pukui 1983:51). The *kōnane* games also drew spectators from all over the island, as is suggested in the next proverb:

Hui aku na maka i Kou.
The faces will meet in Kou.
(Pukui 1983:120)

She explains, "We will all meet there, Kou (now central Honolulu) was the place where the chiefs played games and people came from everywhere to watch" (Pukui 1983:120).

Kukuluāeʻo
Kukuluāeʻo means "to walk on stilts" and shares the name with the Hawaiian Stilt (*Himantopus himantopus*), which would have frequented the marsh area. Pukui et al. (1974) holds that Kukuluāeʻo once fronted Kewalo Basin and described it as being marsh lands with salt ponds and fishponds. Kamakau (1865) states that Kukuluāeʻo was a well-known area in the pre-Contact era with a *heiau* called Puʻukea. Maly et al. (2013) describes the area as near shore.

Kulaokahuʻa
Kulaokahuʻa translates "the plain of the boundary" in Pukui et al. (1974:123). Alternatively, it may be translated as "plain of Kahuʻa," Kahuʻa being the name of a star; or if the *okina* is left out, *kahua* is generally a site for habitation or sports, such as *ʻulu maika* (Pukui and Ebert 1986:113,178). This area consists of the plain that abuts the northern boundary of the project area, defined in the story of Peapea, famed warrior during the time of Kahahana, in Fornander (1819:458) as "the level section between Waikīkī and Punchbowl." Kulaokahuʻa has been described as barren and dry in several accounts (Gilman 1909:9-91; Fornander 1819:458; Pukui 1983:84-85).

Emerson mentions Kulaokahuʻa in the legend of Hiʻiaka, the goddess Pele's sister as she passed through the area:

> ... Their route lay eastward across the dusty, wind-swept plain of Kula-o-kahu'a - destined in the coming years to be the field of many a daring feat of arms; - then through the wild regions of Ka-imu-ki, thickset with bowlders [sic] - a region at one time chosen by the dwarf Menehune as a sort of stronghold where they could safely plant their famous ti ovens and be unmolested by the nocturnal depredations of the swinish Kama-pua'a. Hi'iaka saw nothing or took no notice of these little rock-dwellers. Her gaze was fixed upon the ocean beyond, whose waves and tides they must stem before they reached and passed Moloka'i and Maui, shadowy forms that loomed in the horizon between her and her goal (Emerson 1915:185-186).

The area has been the backdrop of several pre-Contact *moʻolelo*, such as the stories of Pikoi, the rat hunter, Hanaaumoe, the trickster hero, and the story of the famed runner, Kaohele. Kulaokahuʻa was also the setting of several pre- and early Contact battles (Fornander 1819:474; 496; O'Hare and Hammatt 2004:8-9). Kulaokahuʻa has also been referred to as a sports and game playing field. In *The Islander* (Thrum 1875), Kulaokahuʻa is described as a fair ground in which games are played as well as celebratory events in proposing an exposition for the discovery of Hawaiʻi by Captain Cook in 1778:

> Probably the most practical way for to celebrate the occasion, will be to hold a national fair at Kulaokahua grounds in Honolulu, which exhibit all possible Hawaiian resources; which exhibition may be supplemented with sports, match games of ball, boat and canoe racing, &c., &c., [sic] military and other parades, and exercises of a more literary and artistic character, -addresses and music. There is little doubt but that the whole population, natives and foreigners, would enter into such celebration with enthusiasm… (Thrum 1875: Vol. 1; No. 25, p.1).

Thus, the vast plain of Kulaokahuʻa has been well documented in accounts from the pre-Contact era to well into the Historic era.

Kuloloia
The shore of Kuloloia is mentioned by Thrum in the story of *Aiʻai, Son of Ku-Ulla* (Thrum 1900:123-128). In the passage, Aiai walked along the shore of Kulolia to Pākākā and Kapapoko. Maly et al. (2013:42) describes Kuloloia as having been a beautiful sandy beach as well as some of the figures associated with it. Also, a number of *aliʻi* dwelt there and there were *heiau* spread across its shoreline, between Pākākā and Honuakaha. Ī`ī (1959) states that the chiefess Nāmahana lived at the shore of Kuloloia and died in her home. He adds that one of her nephews present during her death was named Kuloloia in afterwards. A single proverb was found referring to Kuloloia in Pukui (1983):

Ka iʻa maunu lima o Kuloloia.
The hand-baited fish of Kuloloia.
(Pukui 1983:149)

As Pukui explains, "Small eels (*pūhi ʻōilo*) that were caught by placing bait on the open palm of one hand with the fingers held wide apart. When the eels came up to take the bait, the fingers were clenched into a tight fist, grabbing the eels tightly by the heads" (Pukui 1983:149). This provides some information on what marine resources were available as well as what fishing methods were used.

Kōʻula
Kōʻula, which translates as "red sugar cane," was a locality in or adjacent to Kewalo (to the north). Maly et al. (2013:41) cite Kamakau (1865) who stated that these lands were cultivated under the orders of the chief, Hua, who is said to have taken care of his people. This land is located partially within the Catholic Cemetery and the Ward property.

Māmala
Māmala, or Kekaiomamala, is the Traditional name for Honolulu Harbor and translates as "fragmented or broken." This bay was the most prominent waterway and boat landing for Kou. As a result, Māmala was the backdrop of many key events and legends of pre-Contact Hawaiʻi. Māmala Bay was named after the famed chiefess who was known to be an ardent surfer. According to Westervelt (1915),

> Ke-kai-o-Mamala was the name of the surf which came in the outer entrance of the harbor of Kou. It was named after Mamala, a chiefess who loved to play konane (Hawaiian checkers), drink awa, and ride the surf. Her first husband was the shark-man Ouha, who later became a shark-god, living as a great shark outside the reefs of Waikiki and Koko Head. Her second husband was the chief Hono-kau-pu, to whom the king gave the land east of the land of Kou. This land afterward bore the name of its chief, Hono-kau-pu. In this section of what is now called Honolulu were several very interesting places (Westervelt 1915:2).

Several proverbs referring to Māmala were found in Pukui (1983):

> He *kai hele kohana ko Māmala.*
> A sea for going naked is at Māmala.
> (Pukui 1983:71)
>
> *Ka nuku o Mālama.*
> The mouth of Mālama.
> (Pukui 1983:163)
>
> *Ke kai ʻau umauma o Māmala.*
> The sea of Māmala, where one swims at the surface.
> (Pukui 1983:184)
>
> *Na ʻale kuehu o Māmala.*
> The billows of Māmala with wind-blown sprays.
> (Pukui 1983:235)

To elucidate the first proverb, Pukui (1983:71) holds that "The entrance to Honolulu Harbor was known as Māmala. In time of war the people took off their clothes and traveled along the reef to avoid meeting the enemy on land." The second proverb refers to a shark goddess who once lived in Honolulu Harbor and is who the entrance is named after. The last two proverbs provide some visuals of what the conditions could be at Māmala and what activities occurred there.

Mauna Kilika
Mauna Kilika, is translated by Maly et al. (2013:44) as "Silk Mountain," which is named for the mounds of silk cloth brought in by foreigners in the Historic era that were often traded for Hawaiian products. Mauna Kilika is also the location of the former residence of Judge Mataio Kekuanaʻoa on the shore of Kuloloia. Mauna Kilika was later named Hale Kauwila. According to Goodale (1897:5), Mauna Kilika was also referred to as the Armory. It was built in 1840 and was one of the first Government buildings in Honolulu. The building is where the Parliament and Land Commission met and is the location of several historical events, including writing of the first constitution.

Pākākā
Pākākā, which means "to glide as on the surf," (Andrews 1922:664) is the Traditional name for the coastal lands at the south end of what is now Fort Street (Īʻī1959). Although the most prominent structure of Pākākā was its *heiau*, several historic accounts speak of houses, likely

those of the *aliʻi*, being located in the area (Īʻī 1959:82). In fact, Pākākā was the location in which Kaʻahumanu and Kaumualiʻi lived together from 1822-25, before Kaumualiʻi died in 1825 (Kamakau 1992:265). The article, "Famous Men of Early Days," in *Fornander's Collection of Hawaiian Antiquities and Folk-lore*, Pākākā is mentioned:

> KEKUAWAHINE was a master hand at deceiving and falsifying; he could turn an untruth into a reality; from correct to incorrect, and so forth. When Kamehameha was residing at Pakaka, Kona, Oahu (that is the place where "White man Jim" lives), at the time that the islands from Hawaii to Niihau were subjugated by him, he was living with his wife, Kaahumanu (Fornander 1917:421).

According to Īʻī (1959:82) the wharf at Pākākā was where people crowded to greet the canoes and boats of Kaumualiʻi upon his arrival to meet with Kamehameha.

Puʻuiki
Puʻuiki translates to "little hill or mound" and is a surf break in Māmala (Maly et al. 2013).

Puʻukea
Puʻukea, which literally means "white hill," is a *heiau* in Kukuluāeʻo, east of Kaʻākaukukui. This *heiau* is said to have been built for Hua-nui-ka-lā-laʻilaʻi, who was born Hua-a-Kamapau at Kewalo (Kamakau 1991: 24-25). In "A Chant for Kualii," Puʻukea is where *mahiki* grass danced (Fornander 1917:396). Pukui and Ebert (1986) maintain that *mahiki* grass is used to exorcise evil spirits.

Puʻunui
Puʻunui translates as "large hill or mound" and is a land division in Nuʻuanu that has several coastal *lele* located from Queen Street past Hale Kauwila Street into Kaʻākaukukui and bounded by South and Coral Streets. These *lele* were known to have salt making ponds.

ʻUlakōheo
According to Maly et al. (2013:48), ʻUlakōheo translates as "Red penis head" and is the name for an area located near the shore between situated near the shore and Queen, Maunakea, Nuʻuanu, and Marine Streets.

Ulukua
Westervelt (1915:3) holds that Ulukua, which was located "near the lumber-yards at the foot of the present Richards Street," was once "the place where idols were made." The waters off of Ulukua is where Kamehameha's single canoe greeted the fleet carrying Kauaʻiʻs regent, Kaumualiʻi (Īʻī 1959:82). Maly et al. (2013:49) states that Ulukua is the site of the Honolulu Lighthouse, which is no longer standing.

Waikahalulu
Translated as "roaring water," Waikahalulu is an ʻili between lower Nuʻuanu and Pauoa Streams as well as below Hale Kauwila Street where it meets ʻĀina Hou, Kuloloia, and Kaʻākaukukui (Maly et al. 2013:49). This area is mentioned in the canoe story where Kakae, a

descendant of Menehune, needed a canoe to search for her brother. Thus, the Menehune built a canoe for her overnight to help Kakae, but did not get it into the water by daylight and left the canoe in a ditch near Waikahahulu (Beckwith 1970:333). Figure 3 illustrates the approximate locations of the *inoa ʻāina* and *wahi pana* in what is now referred to as Kakaʻako.

3.1.4 Heiau of Kakaʻako

Several *heiau*, varying in scale, antiquity, and purpose, once stood in the area now referred to as Kakaʻako. Figure 4 is Rockwood's artistic rendering of Papaenaena Heiau, which was a *luakini heiau* once located in Waikīkī.

Pākākā Heiau

Pākākā Heiau was located west of the south end of Fort Street and was built sometime prior to the reign of Chief Kakuhihewa (Westervelt 1915:8). Kuhoʻoneʻenuʻu, the principal god of Oahu ruling chiefs, was the god of Pākākā Heiau (Beckwith 1970:29). This *heiau* was also the headquarters for all of Oʻahu's priests and that its walls were "adorned all around with heads of men offered in sacrifice" (Westervelt 1915:8). Thrum (1905:45, 57) also holds that Pākākā Heiau was of the *poʻokanaka* (human head) class and located in Honolulu but the actual site was not found. However, he later states:

> Search for the Pakaka and Kaheiki heiaus mentioned by Kamakau, and classed as pookanaka, has not given satisfactory results, though in a native description of early Honolulu, following the Okuu pestilence of 1804, there was located at Pakaka (known later as Robinson's point), heiaus of a medical class under one Papa, termed "na heiau kahuna lapaau." Kamakau having classed his of this name or location as a sacrificial heiau relieves it from confusion with this medical kahuna school (Thrum 1905:60).

In the "Myth of Haumea as Kamehaikana," (Beckwith 1970:281-282) Kou's ruling chief at the time of Papa and Wākea was Lelehoʻomao, who attempted to sacrifice Wākea at Pākākā Heiau for his crime of trespassing.

A prominent *kōnane* playing area and famous boulder was located on one side of the *heiau* (Westervelt 1915:8). In the Historic period, Pākākā Heiau came under the ownership of Kinau, mother of Kamehameha V (Westervelt 1915:8).

Kaheiki Heiau

According to Beckwith (1970:332) Kaheiki Heiau "built by the Menehune and presided over by the kahuna who founded the priesthood called Moʻo-kahuna." A foreigner called, Kahanai-o-ke-akua (Adopted by the gods), was raised by Kane and Kanaloa at Waolani heiau before residing at Kaheiki (Beckwith 1970:332). Kamakau (1961:292) reiterates a story where Boki is warned against disturbing a large boulder in the stream that is the guardian of Kaheiki, lest bad luck befall him and to the surrounding areas.

Beckwith (1970:345) summarizes as story told by Westervelt (1915) about a cannibal "dog-man," named Kaupe, who lived at Lihue on Oʻahu. The story of Kaupe involves a great *kahuna* from Kaheiki Heiau. The story is as follows:

> Among dog-men represented as overthrowing the chief of a district and terrorizing the country, the most famous is the cannibal dog-man Kaupe who overthrew the government of Ka-hanai-a-ke-akua (Reared by the gods) and ruled the land from Nuʻuanu to the sea.
>
> Kaupe lives at Lihue on Oahu. He never attacks a high chief but eats some of the people both of Oahu and Maui. At last he crosses over to Hawaii and brings back a chief's son to sacrifice in the heiau at Lihue. The father follows to Oahu and consults Kahilona, the great kahuna at the heiau of Kaheiki just below the hill called today Pacific Heights, which was built by the Menehune and which becomes under Kahilona the center for the moʻo-kahuna class of priests; that is, for kilokilo who read the signs of earth and sky and sea. This kahuna teaches the chief from Hawaii the prayer to recover his son, which runs
>
> "O Ku, O Lono! O Kanaloa!
>
> By the power of the gods, by the strength of this prayer,
>
> Save us two, save us two!"
>
> The prayer unfastens the boy's fetters and father and son flee and hide under a rock at Moanalua while Kaupe goes on to look for them on Hawaii. The father learns the prayer for killing an enemy, and overcomes Kaupe on Hawaii (Beckwith 1970:345).

Puʻukea Heiau

The name Puʻukea literally means "white hill" and is said to be a *heiau* built under the management of a chief named, Hua-nui-ka-lā-laʻilaʻi, who hailed from Kewalo. This chief was born under the name Hua-a-Kamapau, but received the name from his subjects for his benevolent rulership (Spearing et al. 2008; Maly et al. 2013).

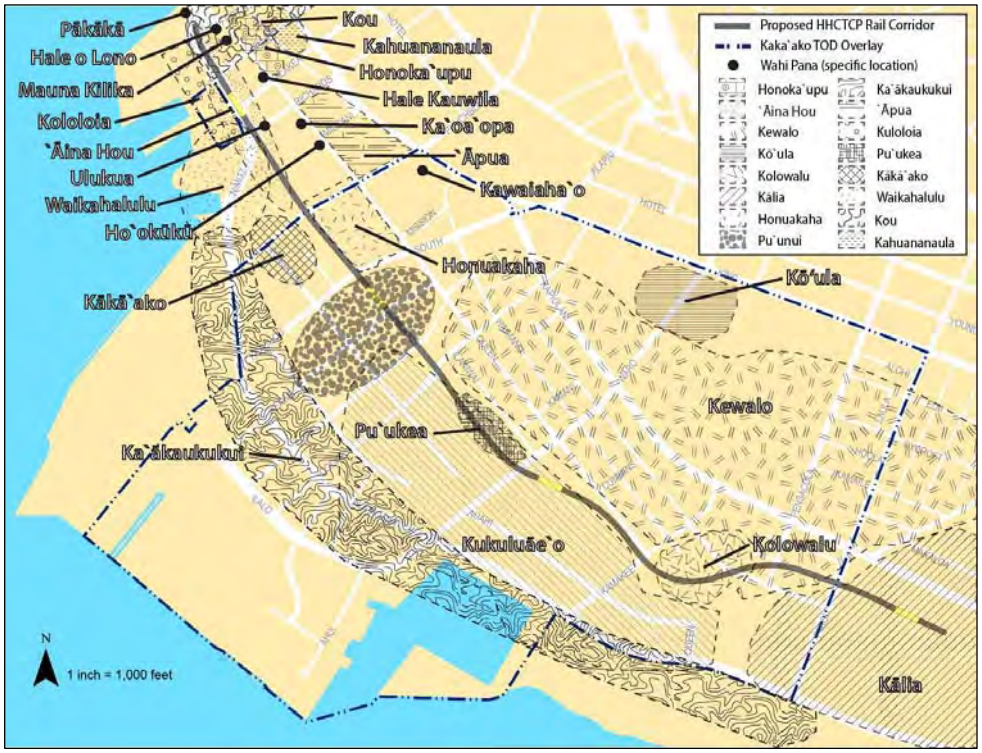

Figure 3. ***Inoa ʻāina*** **&** ***Wahi Pana*** **in Kakaʻako and vicinity.**

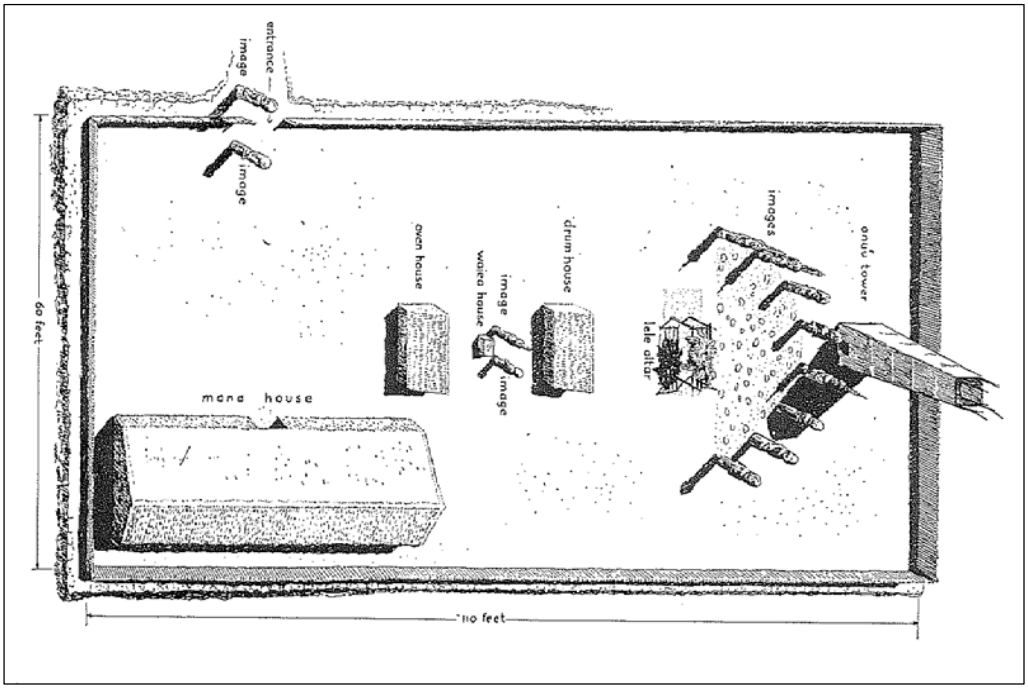

Figure 4. Rockwood's rendering of a ***luakini heiau*** **(in Īʻī 1959:34).**

3.2 POST EUROPEAN CONTACT CULTURAL LANDSCAPE

The islands of Hawai'i have undergone dramatic changes since its discovery by Native Hawaiians, which is now debated to be no earlier than 1200 years before present (Kirch and McCoy 2007). The arrival of Europeans in the late 1700s sets the scene for a different drama to unfold (Figure 5). After European contact until the present, Kaka'ako has gone through even more radical changes in the physical and cultural landscape due to the decline of the Native Hawaiian population and the increasing influence of Western and Asian immigrants. In this period, Kaka'ako has gone from a hinterland between the two major localities, Kou and Waikīkī, to the governmental seat and recreational area of O'ahu's royalty and *ali'i*, subsequently, the urban and industrial heart of the island.

Figure 5. Early Historic Image of East Honolulu (Bates 1854:95).

3.2.1 European Contact

Previous cultural studies (Spearing et al. 2008; Vogeler et al. 2010; Genz & Hammatt 2010; Elison and McElroy 2011; Maly et al. 2013) have documented scores of early Contact observations and anecdotes for the region now referred to as Kaka'ako. This Supplemental CIA provides additional early references to the physical environment, events, and people of the area.

The earliest written reference to the Island of O'ahu was recorded by Captain James Cook in 1778, where he described O'ahu as "…the most Easterly of these islands, seen by us…we could get no other intelligence, but that it is high land, and is inhabited" (Cook 1784:222). Following

Captain Cook were Captains Portlock and Dixon of the HMS King George and Queen Charlotte, who interacted with the inhabitants of the island as described by Calcott et al.:

> Captains Portlock and Dixon 1786, were the first followers of Cook: they, being on a trading voyage to the Northwest coast for furs, procured refreshments at Oahu; and about the same time La Perouse visited Maui: from that year ships frequently touched there. The natives, profiting by their intercourse with them, had become so sensible of the utility of our vessels, that they had boldly attacked a brig and a snow [sic]; and actually did possess themselves of a small American schooner, the crew of which, with the exception of one man, they murdered. Isaac Davies, the fortunate person who escaped, was mate of the vessel. He had been ashore at the time of the capture, and took refuge with the king of Hawaii, who treated him most kindly, and in whose service he remained (Calcott et al. 1826:29-30).

Portlock and Dixon provided the earliest written accounts of topographical features and inhabitants of O'ahu's south coast, possibly from the bay of Waikīkī or Kou:

> The island of Woahoo between the South East and North East points appears high and craggy forming into several high rocks within which there appears to be tolerable shelter but as the wind blew fresh and right on shore, I did not think it prudent to run in with a lee to look for anchorage.
>
> We plied in this uncertain state till noon on the 1st of June when finding it would be impracticable for us to get round the North East point of the island without wasting more time than could be spared we bore away for the South East point; and at one o clock being well up with it, a fine bay made its appearance, which promised to afford good anchorage. We hauled round the point and stood in for the bay. Soon afterwards the whale boat was lowered down and sent in shore to sound. At half past two o clock we came to an anchor in the bay which I distinguished by the name of King George s Bay, in twelve fathom water, over a bottom of speckled sand and broken shells…
>
> Soon after our arrival, several canoes came off and brought a few cocoa-nuts and plantains, some sugar-cane and sweet root; in return for which we gave them small pieces of iron and a few trinkets. Towards evening, a fresh breeze coming on at East North East, our visiters [sic] left us, and returned on shore.
>
> Next morning at daylight we had several canoes about the ship, which brought us a few small hogs and some vegetables. Great numbers of both sexes were in the water, impelled by curiosity to pay us a visit, notwithstanding our distance from shore (Portlock 1789:68-70).

At about the arrival of Europeans in 1778, nearby Waikīkī was densely populated, verdant, and prosperous. One observation given by Captain George Vancouver in 1792 upholds this view of the post-Contact period Waikīkī. Vancouver states:

> …in this bay, which the natives call Whyteete, seemed nearly as eligible as most of the anchoring places these islands are generally found to afford…On the

> shores, the villages appeared numerous, large, and in good repair; and the surrounding country pleasingly interspersed with deep, though not extensive valleys; which, with the plains near the sea-side, presented a high degree of cultivation and fertility…our guides led us to the northward through the village, to an excavation exceedingly well-made causeway, about twelve feet broad, with a ditch on each side… This opened to our view a spacious plain, which, in the immediate vicinity of the village, had the appearance of open common fields in England; but on advancing, the major part appeared to be divided into fields of regular shape and figure, which were separated from each other by low stone walls, and were in a very high state of cultivation …planted with the eddo or taro root, in different stages of inundation…some from three to six or seven inches under water…At Woahoo, nature seems only to have acted a common part in her dispensations of vegetable food for the service of man; and to have almost confined them to the taro plant, the raising of which is attended with much care, ingenuity, and manual labour…(Vancouver 1798: I, 161- 164).

Vancouver's descriptions illustrate the intensity of agriculture in *mauka* Waikīkī as well as the fitness of its irrigation and infrastructure at the period of European Contact. Archibald Menzies, who travelled on the Vancouver Expedition as a surgeon and naturalist also commented on the flourishing state of Waikīkī at this time period:

> … the shore was planted with a large grove of cocoanut palms, affording a delightful shade to the scattered habitations of the natives. Some of those near the beach were raised a few feet from the ground upon a kind of stage, so as to admit the surf to wash underneath them. We pursued a pleasing path back to the plantation, which was nearly level and very extensive, and laid out with great neatness into little fields planted with taro, yams, sweet potatoes, and the cloth plant. These, in many cases, were divided by little banks on which grew the sugar cane and a species of Dracena without the aid of much cultivation, and the whole was watered in a most ingenious manner by dividing the general stream into little aqueducts leading in various directions so as to be able to supply the most distant fields at pleasure, and the soil seemed to repay the labor and industry of these people by the luxuriancy of its productions. Here and there we met with ponds of considerable size, and besides being well stocked with fish, they swarmed with water fowl of various kinds such as duck, coots, water hens, bitterns, plovers, and curlews…They frequently offered us both musk and water melons, which they thought might be more acceptable to us as they received the seeds from Britannee…On returning to the beach after a circuit of about three miles, we found that they had dressed hogs and taro for us, but as we had neither time nor much inclination to eat anything, they insisted on packing them up cleanly in leaves and putting them into our boats (Menzies 1920: 23-24).

An earlier account of Waikīkī given by Captains Portlock and Dixon in 1785, offers interesting commentary on the pre-Contact Hawaiian religion and culture, which follows:

> Next morning at eight o'clock the long-boat came along-side, and Mr. Hayward informed me, that on going down to the place where his guide conducted him in Queen Charlotte's Bay, he found a small bay with very deep water, close to a sandy beach, where the natives generally landed with their canoes, but no place

> for a ship to ride in with safety ; adjoining to the beach, in a beautiful valley, surrounded by fine groves of cocoanut trees and a delightful country, there was a large town, where (as Towanooha informed him) the king generally resided, and the district round it was called Whyteetee. According to Mr. Hayward's account, there were very few canoes in the bay; neither did he see any great number of inhabitants; so that we may reasonably suppose they were come into the bay where we lay, led either by business or curiosity.
>
> Not a single native came near the ships for two days, and their canoes were hauled out of sight, but we could perceive vast numbers of the inhabitants about the house on the hill. During this time our people were busily employed about the rigging, and getting the ship ready for sea.
>
> At daylight in the morning of the 17th the old priest, attended by his yava-chewer Towanooha, came on board. The old man seemed quite enraged at the king's recent conduct; he told me that the king and all his principal chiefs had been making offerings to their gods, and consulting them; but that the gods were good for nothings and that the king and his adherents were no better than villains, for intending to do us any mischief, after the many presents they had received from both ships. I thanked my old friend for his intelligence, and told him that we should be constantly on our guard.
>
> For some days past I had been strongly importuned by Towanooha, and a very fine young man of the first consequence in the island, who was a constant companion of the king's, to take them along with me to Atoui; and indeed Taheeterre had more than once urged me to take them; but I never thought they were in earnest until this forenoon, when the young chief, whose name is Paapaaa, came on board, and joined his entreaties with those of Towanooha in so very pressing a manner, that I promised to take them on board; and they returned on shore in order to prepare themselves for the passage. The yava-chewer, being now as it were a gentleman passenger, no longer considered himself as a servant, but took to drinking yava heartily, and laid in a plentiful stock of that root.
>
> In the afternoon we had a fresh gale from the East North East, with frequent squalls, which prevented any canoes coming near us. Towards evening I observed the natives uncovering and pulling to pieces their new built house on the hill ; and about eight o'clock several large houses were on fire along shore near the bay ; but as we had no Indians on board, I could not learn whether they were set on fire by accident or design, till the next morning, when the old priest and our two passengers coming on board, I enquired the reason of the fires we had seen on shore the preceding evening; and was given to understand, that they were Eatooa's, or houses belonging to gods with whom the chiefs were displeased; therefore out of revenge they had burnt gods and houses both together. In the forenoon a great number of large and small canoes came off and brought us a tolerable supply of various sorts of vegetables and a few hogs. Since our water was completed, having expended several casks, I directed the natives to bring us a further supply, which they very soon did in great abundance.

> The king also, with his retinue, paid me a visit; at his first coming on board he seemed rather shy, but upon the whole he conducted himself nearly in his usual manner. On my taking notice of the red house on the hill he appeared a good deal confused, and waving that conversation, begun to talk about his two countrymen who were going with me to Atoui. He seemed very much interested in Paapaaa's welfare; he particularly requested me to take care of him and treat him well, and if we flopped at Atoui, he begged that I would leave him under the care of Taaao, who it seems is brother to Taheeterre, and a relation of Paapaaa's. The two passengers asked me for a few trifles to leave amongst their friends before they set off, which I readily gave, and also made the king a present; on which he took leave of me for the last time, and after taking a very affecting one of his countrymen, particularly of Paapaaa, he quitted the ship and went on shore; the other canoes remained alongside to dispose of their cargoes, and we procured a supply of good hogs, which enabled me to set the falters to work again. In the afternoon the rigging was set up, the fails bent, and every thing ready for sea (Portlock 1789:164-167).

The fact that King Kamehameha I had begun his campaign to unify the islands in the early 1780s may explain some of the drastic changes befalling the social structure and religion of Oʻahu at this time.

Captain Vancouver (1798) also recorded his interactions with European seamen from the American sloop, Lady Washington, whom had been living on Oʻahu and other islands to arrange sandalwood and pearl exports prior his arrival on Oʻahu in 1792, stating:

> At Woahoo and also on our arrival here we were given to understand that there were Englishmen resident on this island.
>
> One of them a young man about seventeen years of age, whose name was Rowbottom, came on board in a large double canoe; who said he was of Derbyshire, that he had sailed from England about five years since in an Indiaman to China, which ship he had quitted in order to engage with some of the vessels in the fur trade between North-West America and China; and that he had, ever since, been thus employed in the American service. He informed me, that himself, John Williams, a Welchman, and James Coleman an Irishman, had been left at Onehow, in order that they might return to this island for the purpose of collecting sandal-wood, and pearls, for their master John Kendrick, an American, commanding the brig Lady Washington, in whose service they still remained at the wages of eight dollars per month. The Lady Washington had quitted these islands the preceding October, bound to New England, with a cargo of furs to dispose of in her way thither at China; she was immediately to return from Boston, and having spent the next winter in North-West America, was, in the autumn of the ensuing year, to call for these men at Attowai, and take in a cargo of sandal-wood for the Indian market, with such pearls as they might have collected (Vancouver 1798:172).

In March of 1794, Vancouver (1798) wrote in his journal about the short survey he made from sea of the island of Oʻahu. Vancouver had planned on landing on the island during this sojourn; however, due to heavy surf they were only able to investigate the north shore and

southeast point of the island before heading to the island of Kauaʻi. At Kauaʻi, Vancouver joined an American brig, the Lady Washington, whose crew members had gone ashore for five days at Waikīkī just days prior. He states:

> Here we rejoined the American brig Washington, which had sailed with us from Karakakooa, but had directed her course to the southward of the islands, for Whyteete in Woahoo, where she had remained five days. Amongst other articles that Mr. Kendrick had procured whilst there, was eighty pounds weight of very fine bees wax, that had drifted by the sea on to the shores of that island, and had very recently been picked up by the natives; and I now understood that some pieces had also been procured from the natives of the other islands by Mr. Kendrick, who in a great measure confirmed the account contained in Mr. Brown's letter to me, of the very improper conduct of the merchant seamen who had deserted, or otherwise quitted the vessels to which they had belonged, for the purpose of residing amongst these islanders. In this number were some whom we had formerly left at Attowai but he now seemed to be determined that they should no longer remain on that island (Vancouver 1798:121-122).

These early commentaries provide an idea of how much interaction with Europeans the Native Hawaiians had prior to the first written accounts.

3.2.2 Kakaʻako in the 19th Century

The 19th Century proved to be a time of total transformation for the area now referred to as Kakaʻako. Traditional Hawaiian dwellings, transportation, and cultural practices quickly succumbed to Western customs – forever changing the people and their landscape from Kou to Waikīkī and *mauka* to *makai*. Figures 6 and 7 provide a glimpse of what the early 19th Century Kakaʻako vicinity landscape was like.

The earliest European visitors found two major Hawaiian settlements flanking Kakaʻako as we know it today: Kou (now Honolulu) and Waikīkī. Kou was depicted as having ample coastal fishponds and irrigated agricultural areas. Waikīkī, the initial governmental seat, had a complex system of *loʻi kalo* (taro patches) and *auwai* (irrigation ditches) that extended across the *kula kai* (seaward plain) as well as coastline studded with fishponds. Most early 19th Century descriptions of the area focus on either Kou or Waikīkī, yet, some accounts of travels between the two localities were recorded. An early 19th Century passage from the journal of Archibald Campbell, a Scottish-born seaman on board the merchant ship, Thames Indiaman, describes his first impression of Honolulu (Hanaroora) in 1809:

> Three miles to the west of Whyteete is the town of Hanaroora, now the capital of the island, and residence of the king. The harbour is formed by the reef, which shelters it from the sea, and ships can ride within in safety in any weather, upon a fine sandy bottom. There is a good channel through the reef, with three or four fathoms water; but if there is a swell it is not easily discovered, as the sea often breaks completely across. Pilots, however, are always to be had; John Hairbottle, captain of the Lily Bird, generally acted as such. The best anchorage is in five fathoms water, about two cables length from the shore, directly in front of the village. Ships sometimes anchor on the outside of the reef, but they run the risk of having their cables cut by the coral (Campbell 1819: 110).

Figure 6. Portion of Von Kotzebue's 1817 Map of South Oahu with approximate project area.

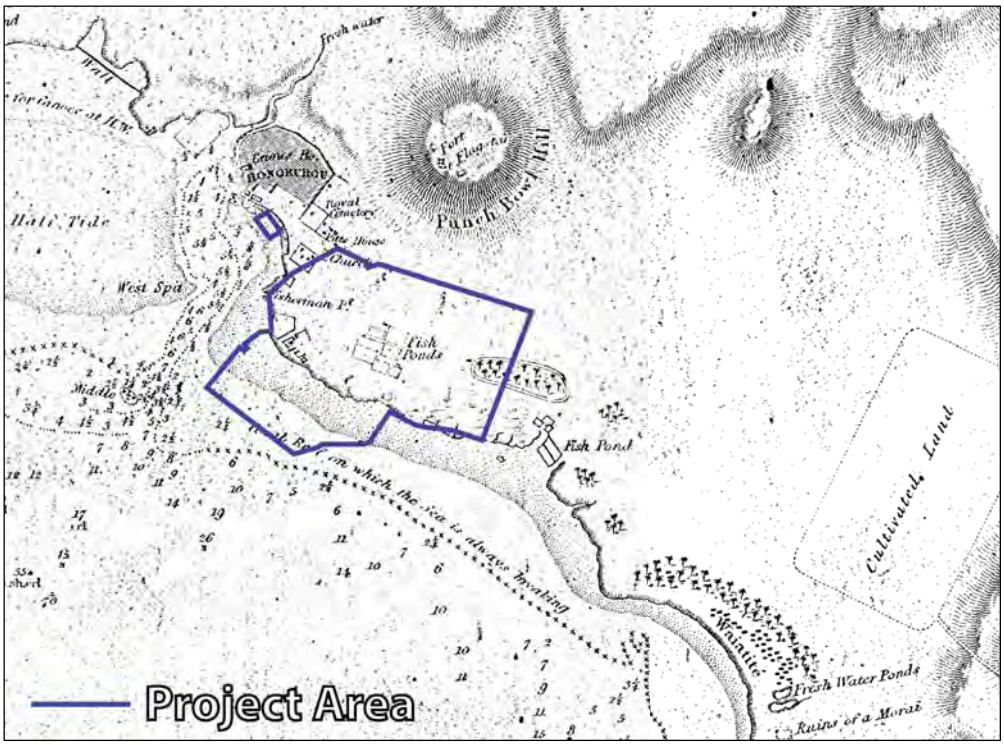

Figure 7. Portion of the 1825 Malden Map of South Oahu with approximate project area.

> The entrance to this harbour may probably, at no very distant period, be filled up by the growth of the coral, which must be rapid indeed, if Hairbottle, the pilot, was correct, when he informed me that he knew a difference of three feet during the time he had been at Hanaroora.
>
> A small river runs by the back of the village, and joins the sea at the west side of the harbor; owing to the flatness of the country, the water is brackish, and there is none fresh to be had within several miles of the place. Ships, however, can be supplied at a moderate rate by the natives who bring it from the spring in calabashes (Campbell 1817:110-112).

Campbell also documented his first encounter with King Kamehameha (Tamaahmaah) and his court in Honolulu:

> Tamaahmaah, king of Owhyhee, Mowee, Wahoo, and the adjoining islands, resided some years at this place. His house, which we could distinctly see from the ship, was built of brick, after the European manner. Of late, he has fixed his residence at Wahoo; upon learning which, the captain determined to proceed thither. […]
>
> A number of natives came off, as usual, the moment the ship hove in sight. King Tamaahmaah was in a large double canoe; on his coming alongside, he sent his interpreter on board to announce his arrival.
>
> The captain immediately went to the gangway to receive his majesty, and shook hands with him when he came upon deck.
>
> He was, on this occasion, dressed as a European, in a blue coat and grey pantaloons.
>
> Immediately on his coming aboard, the king entered into earnest conversation with the captain. Amongst other questions, he asked, whether the ship was English or American? being [sic] informed that she was Russian, he answered, " Meitei, meitei," or, Very good. A handsome scarlet cloak, edged and ornamented with ermine, was presented to him from the governor of the Aleutian islands. After trying it on, he gave it to his attendants to be taken on shore. I nevar [sic] saw him use it afterwards. In other canoes came Tamena, one of his queens, Crymakoo, his brother-in-law, and other chiefs of inferior rank.
>
> My appearance attracted the notice, and excited the compassion of the queen; and finding it was my intention to remain upon the islands, she invited me to take up my residence in her house. I gladly availed myself of this offer, at which she expressed much pleasure; it being a great object of ambition amongst the higher ranks to have white people to reside with them. When the ship was brought to anchor, she sent me ashore in one of her canoes. […]
>
> Upon landing I was much struck with the beauty and fertility of the country, so different from the barrenness of the Fox islands [sic]. The village of Hanaroora, which consisted of several hundred houses, is well shaded with large cocoa-nut

> trees. The king's residence, built close upon the shore, and surrounded by a pallisade [sic] upon the land side, was distinguished by the British colours and a battery of sixteen carriage-guns, belonging to his ship, the Lilly Bird, which at this time lay unrigged in the harbour. This palace consisted merely of a range of huts, viz. the king's eating-house, his sleeping-house, the queen's house, a store, powder-magazine, and guard-house, with a few huts for the attend ants, all constructed after the fashion of the country.
>
> At a short distance were two extensive store-houses, built of stone, which contained the European articles belonging to the king. (Campbell 1817:85-88).

Sadly, Campbell had both of his feet amputated just prior to landing in Hawaiʻi. Campbell (1817) describes the hospitality of Kamehameha and his court during his 1809 visit to Honolulu:

> I was conducted to the house occupied by the two queens. It consisted of one large apartment, spread with mats; at one end of which the attendants of both sexes slept, and at the other the queens occasionally slept when the king was in the morai.
>
> They and their attendants always eat here, and Tamena wished me to join them; but as I had been informed by Crymakoo, that if I did so, I should not be allowed to eat with men, I resolved to decline her offer. […]
>
> His principal chiefs being always about his person, there were generally twenty or thirty persons present; after being seated upon mats, spread on the floor, at dinner, a dish of poe, or taro pudding, was set before each of them, which they ate with their fingers, instead of spoons. This fare, with salt fish and consecrated pork from the morai, formed the whole of the repast, no other food being permitted in the king's house. A plate, knife and fork, with boiled potatoes, were, however, always set down before Moxely and me, by his majesty's orders. He concluded his meal by drinking half a glass of rum, but the bottle was immediately sent away, the liquor being tabooed, or interdicted to his guests. The breakfast and supper consisted of fish and sweet potatoes. […]
>
> When the king was absent on these occasions [ceremonial obligations], I did not experience the same attention as at other times; the attendants became very remiss in providing my dinner, and I was sometimes obliged to go without it altogether (Campbell 1817:89-92).

Campbell's account speaks to the kindness that King Kamehameha I afforded him, possibly due to his condition. Campbell also wrote of the king's men carrying him about on their shoulders as well as the king granting him lands in the Waimano area of ʻEwa just before he journeyed back to Europe (Campbell 1817).

Honolulu, the inhabitants of Honolulu, King Kamehameha I, his royal court, and the royal residence were further described in 1822 by the English writer and world-traveler, Gilbert Farquhar Mathison (1824), albeit laden with Western bias:

At two o'clock P. M. we could plainly distinguish the huts, canoes, and persons of the natives on the sea-shore — some employed in fishing, others in mending their nets. The shipping and smoke of Hannah-rourah, the capital of the Sandwich Islands, soon after came into view, and the approach of some boats and canoes kept us all in a state of agreeable excitement. At three o'clock we anchored in the roadstead, and received visits from several American residents. They assured us that no danger was to be apprehended from the natives, with whom they had been accustomed to live upon the most amicable footing, and that some Missionaries and their families were likewise established there. Mr. Jones, the American Consul, kindly offered me accommodation for the night, which I accepted, and immediately accompanied him on shore, leaving my fellow-passengers, who were less eager and impatient, to follow the next day.

Upon landing, we were immediately surrounded by a mob of men, women, and children, who pressed forward to shake me by the hand, and eyed me with great apparent curiosity. They were all dressed *au naturel*, or nearly so, with nothing but the maro, a cincture of cloth made from the paper mulberry-tree, round their waists; their cries were most discordant, and the clatter of women's tongues not the least audible. I afterwards found out that they were settling a nickname for me, in allusion to some peculiarity in my dress or person. This they do invariably, whenever a stranger comes among them; and it is astonishing how quick-sighted, and even witty, they often are, in ridiculing the least affectation of manner, awkwardness of gait, or bodily deformity.

Having thus encountered their jokes on first landing, I went with the Consul to the palace of the King, if such a term can be applied to a grass hut, floored with mats, and only distinguished from the rest by a few cannon placed about it *in terrorem*. Imagination had pictured the monarch, sitting in the midst of his chiefs with dignified composure, his interpreter on one side and secretary on the other, (for he really has two such officers); and, as the subject of a brother king, I anticipated a most gracious reception. What, then, was my astonishment on entering the royal hut! "Oh, majesty! Oh, high ambition, lowly laid I" The royal beast lay sprawling on the ground in a state of total drunkenness and insensibility. On one side of his head was extended an enormous sow, which every now and then gave a grunt, as if in sympathy with its master; and upon the other side sat his Queen, an immense woman, like him, almost in a state of primitive nudity, who seemed endeavouring, though in vain, by her caresses, to assuage his beastly transports: a few chiefs and domestics, in all about twenty, completed the group — some asleep, others fanning away the flies, and singing the wildest and harshest lullaby that ever saluted mortal ears.

We then passed into another room belonging to the head Queen; who, though equally large in her person, had a benevolent and pleasing cast of countenance. She was dressed in a loose robe of English chintz, and, to my delight, was engaged in learning to write, which she had only attempted within a few days. She showed me her performance on the slate with great eagerness; and well she might, for really the letters were by no means badly formed. I then underwent, as on my first landing, a thorough examination, during which her Majesty often laughed immoderately, and ended her remarks by saying that I was a mere child, and had no beard.

The ground part of the apartment was matted, and the walls hung round with mats, with a large and handsome mirror on one side, and upon the whole had a comfortable appearance ; though the furniture, comprising several Chinese chests, a mahogany table, and three matted bedsteads — in addition to the living furniture, comprising her Majesty the Queen and her numerous attendants, who lay extended on the floor in different attitudes, and kept up an incessant singing sort of noise- gave to the whole scene a truly fantastic character.

Mr. Jones accommodated me at night with a bed in his hut, and introduced me the next morning to the other American residents, who were all seafaring men, and had come to this place to carry on a trade for sandal wood (Mathison 1824:362-366).

Mathison's account provides a lens in which early European visitors viewed Native Hawaiians. As people and customs were described, the early 19th Century landscape of what is now considered Kakaʻako were also documented by several early visitors to the locality. Mathison (1824) later described the countryside during his walk from Honolulu to Waikīkī in 1822:

After dinner this day I went ashore and walked with a friend to Whyteete, a village on the sea-side, about five miles from the port. Our route lay first over an open plain, but we afterwards passed through cultivated fields, which are divided from each other by embankments. They are very extensive, and are planted with the tarrow-root, which appears to be the principal or rather sole object of cultivation. Artificial irrigation is essential to the growth of this plant, upon which, in a great measure, the Sandwich Islanders subsist. It is regularly planted in rows, each one or more in a little bed of soft mud surrounded by water; and the whole field being inundated, banks from two to three or four feet in height are raised on every side, so as to keep the water within proper limits, and at the same time make a partition of property (Mathison 1824:373-374).

In 1823, Reverend William Richards of Plainfield, Massachusetts, and fellow missionary, Charles Stewart of Flemington, New Jersey, arrived in Hawaiʻi. After spending some time in Honolulu, the two sailed to Maui and described the contrast between the two localities:

The thick shade of the bread fruit trees which surround his cottages the rustling of the breeze through the bananas and sugar cane the murmurs of the mountain streams which encircle his yard and the coolness and verdure of everything around us seemed in contrast with our situation during a six months voyage and four weeks residence on the dreary plain of Honoruru [sic] like the delights of an Eden and caused our hearts to beat warmly with gratitude to the Almighty Being… (Richards and Stewart 1823:39).

Another, somewhat contrary, account of Kakaʻako's coastal area and abundant fishponds in the early historic period was provided by Andrew Bloxam, who was the naturalist on the HMS Blonde in the mid 1820s. Bloxam stated in 1825:

…The whole distance [along the coast from Honolulu] to the village of Whyteete is taken up with innumerable artificial fishponds extending a mile inland from

> the shore, in these the fish taken by nets in the sea are put, and though most of the ponds are fresh water, yet the fish seem to thrive and fatten. Most of these fish belong to the chiefs, and are caught as wanted. The ponds are several hundred in number and are the resort of wild ducks and other water fowl. It is pleasantly situated and built along the shore among numerous groves of coconut and other trees, and in this respect far better than Honoruru, as scarcely any trees are to be found there. Diamond Hill, the southeast point of the island, is about two miles beyond… Near one of its sides are the remaining walls of an old morai or temple; the sea washes its base and hence it forms a good landmark for ships (Bloxam 1925: 35-36).

The early 19th Century was a period of raid period of population growth in the area now known as Kakaʻako. In 1820, Protestant missionaries associated with the American Board of Christian Foreign Missions (ABCFM) first arrived in the Hawaiian Islands. A comment on the demographics of early Honolulu and the embrace of Christianity by its people was provided in a letter by the Joint Missionaries in Hawaiʻi to the ABCFM in 1823, stating:

> Honoruru, the present seat of government, occupies about one square mile and contains about 550 houses. Allow 50 to be uninhabited, and allow eight souls to each house of the remaining 500, including persons who are present from other districts and other islands, and the number of souls a the village of Honoruru is 4,000. It is truly animating to see one fourth of this number including the king and several of the principal chiefs of the islands, come out on the Sabbath to the place of worship, filling the house to overflowing and thronging the doors and windows, as if they would know what our new doctrine is (Joint letter of the Missionaries 1823:314).

In the 1820s, a surge in population, commerce, industry, and government was seen in Honolulu. In an article titled, "The Early Streets of Honolulu," Gillman describes Pākākā as a busy maritime community as well as the location that male and female convicts were hung before becoming a shipyard in the 1827, stating:

> Before describing Fort street [sic] we will take a look at the famous premises of James Robinson & Co., at that time the only ship builders and repairers on the islands and in fact in the Pacific. It was a rather peculiar partnership in the make up of the firm which began in 1822, though the shipyard at the point, "Pakaka," was not established till 1827. The firm comprised Jas. Robinson, Robt. Lawrence and Robt. Holt. The two former were together in the Hermes, which vessel with the Pearl, set forth from this port on a whaling cruise, and both ran ashore twenty days out on an unknown reef afterwards named for the lost vessels. Mr. R. built a schooner from the wrecks in which with eleven others he reached these islands in Oct. 1822. This vessel was the foundation of their subsequent business and fortune. Mr. Robinson, the senior of the firm, was considered a ship carpenter of skill and ability; Mr. Lawrence, familiarly called "Bobby," was the book keeper, house keeper, and general steward of the establishment. Some of his boarders, all men, used to remark that the bread which he made occasionally tasted of the oakum which he was in the constant habit of picking from bits of tarred rope which he carried in his pocket. Mr. Holt was an American and much the best equipped for managing the business of the partners. They occupied for

> their headquarters a two-story stone building under the walls of the old fort, the lower part unoccupied except for storage, the upper part used as office and living apartments. At the time of the death of the last surviving partner, Mr. James W. Austin, who was their attorney, went into the lower part and, guided by some directions, unearthed a large amount of coin which had been secretly and safely buried there.
>
> Proceeding along Queen street [sic] on the makai side, we come to the old fort. This is so historically well known that it needs no description from me. Its walls extended along the street to some distance past Fort street [sic], at the foot of which the large gateway- served for entrance and exit. Over this gateway on two occasions were erected scaffolds for the execution of two couples, men and women, for having committed murder. Indicative of the natives' superstition was an incident connected with the last execution. The streets near and approaching the fort were packed with natives, men and women, who had come from all parts of the island to witness the execution. They had waited as patiently as could be expected for the appearance of the criminals, but the moment that the drop fell, and it was evident that they had paid the penalty of their crime with their lives, the people as if actuated by one common thought, cried out "Ghosts, Ghosts," and ran like a flock of frightened sheep in the opposite direction as fast as their legs could carry them, and in a short space of time the streets were cleared (Gilman 1900:81-82).

The sandalwood trade was an important element in the growing economy of Honolulu. Thrum (1905) describes such areas as Pākākā and Kakaʻako as important localities in the Oʻahuʻs early sandalwood trade:

> Some years before the arrival of Alex. Adams[1] search was made in the mountain forests for sandalwood. Because of the fragrance of the naio[2] it was supposed that it would meet the demands, therefore, this variety of wood was taken to China, but found to be worthless. In consequence of this the iliahi was assured to be the wood wanted, whereupon diligent search in the forest stretches of these islands was made, and there was sent on certain American vessels this desired kind of wood. There were three three-masted vessels which sailed for China, and each vessel took several natives to help on the voyage and in their discharge at China.
>
> Upon the return of the vessels they anchored off Mamala[3] while the boats passed on from ITaka[4] to Pakaka[5]. The boats were gaily decorated, and the men wore soldiers' red coats and had shiney [sic] hats on their heads. They were thought to be foreign man-o-war's men when in fact they were the returned Hawaiians from China. Men, women and children gazed at them from below Kakaako, Pakaka and other places, as they strolled about, for it was the first known of these new things in Honolulu. "Wonderful indeed"! was the expression of the time. But these and all other things of the kind were Kamehameha's.
>
> Being assured that the sandalwood of these islands had real value, large numbers of the people throughout the group were sent to collect it, and it became the article of trade. And because of this, vessels came to these harbors continuously from that time. It was thought that upon Kamehameha's removing to Hawaii a

large increase in sandalwood trading vessels would follow, for these captains took frequent cargoes of it to China whereby, it was said, their owners became very wealthy. And thus it probably was with the majority of the vessels which traded for sandalwood at the various ports. * *

It is said that an agreement was made between the king and the captain that conveyed the chiefs in their inter-island travels, to load up the Lelepali[6] with sandalwood and dispose of it and the vessel, for it was becoming old. This plan was carried out and a foreigner of good standing was placed in charge thereof and sailed for China. * * *

In due time there returned here the one who took the Keoua Lelepali with sandalwood to China, and it is said he placed in the hands of the king $10,000. If the report is true there is ground for belief in the foresight of the king in his course with the vessels and Americans, as has been shown.

1 Captain Alex. Adams arrived at the islands in 1816.
2 Bastard sandalwood — Myoporuin sandwicensis.
3 The anchorage outside the spar buoy.
4 Light house point.
5 Robinson's point.
6 Known also as Keoua Lelepali.
[Note: ** and *** were not defined]
(Thrum 1905:278)

A sad commentary was made by early missionary, Levi Chamberlain, on the state of the Native Hawaiian population in the 1830s, which was ravaged by disease for several years prior, during his tour around the island of O'ahu. Chamberlain's journal states:

…The view here given of the apparent of population at this group of islands, the evidence that former generations of natives were less vicious, more civilized, industrious, and more happy, than the generation which the missionaries found there, agrees with what has been written on same subject by others. There is in every part of the heathen world which been explored that the people were more wicked, more superstitious, more ignorant of the arts of civilised [sic] life, more debased in their affections, and more miserable; and so they will probably continue to do, until the gospel arrests this progress in degeneracy. Captain Cook estimated the population the Sandwich Islands at 400,000 while at present it does not exceed 150,000. Pestilence, wars, infanticide (extending to two thirds of all the children born), and prevailing depravity, are the causes assigned for this decrease. The scene here described by Mr. C is a few miles east of Honoruru.

Our path led us along the borders of extensive plots of marshy ground, having raised banks on one side or more, and which were once filled with water, and furnished abundantly with esculent fish, but now overgrown with tall rushes waving in the wind. The land all around for several miles has the appearance of having been once under cultivation. I entered into conversation with the natives respecting its present neglected state. They ascribed it to the decrease of population. There have been two seasons of destructive sickness, both within the period of thirty years, by which, according to the account of the natives, more

than one-half of the population of the island was swept away. The united testimony of all of whom I have ever made any inquiry respecting the sickness, has been, that 'Greater was the number of the dead than of the living.' Making due allowance for the hyperbolical manner in which the natives sometimes express themselves, it may, I think, be safely asserted, that since the discovery of these islands by captain Cook there has been a decrease of population by desolating wars, the ravages of disease, and other causes, equal, at least, to one-half the number of the inhabitants that might have been fairly estimated at the time that celebrated voyager last visited these islands (Chamberlain 1957:26).

In the mid-19th Century, Hawai'i also underwent perhaps, the most drastic changes to traditional Hawaiian land use, cultural practices, and politics. In 1845 and 1846, The Organic Act paved the way for the Māhele 'Āina, which introduced the concept of private property into Hawaiian society. The lands, traditionally held in stewardship by the *ali'i* (chiefs) of Hawai'i were divided in 1848 under Kamehameha III. Land titles, or Land Commission Awards (LCA), were granted by the Board of Commissioners also known as the Land Commission (Chinen 1958). In 1848, the crown, the Hawaiian government, and the *ali'i* received their land titles. As a result of a general misunderstanding of new land ownership laws and influence of alcohol during transactions, many Native Hawaiians lost rights to lands that they inhabited and farmed for generations. Despite the loss of land rights that many Hawaiians suffered from the Māhele'Āina, LCA and the documents supporting these claims, such as applications, Native Testimonies, and Foreign Testimonies afford a glimpse of how these lands were used traditionally.

The area now referred to as Kaka'ako contained numerous LCA (Spearing et al. 2008; Genz & Hammatt 2010; Elison and McElroy 2011; Maly et al. 2013; Hammatt 2013) with a total of 80 LCA falling in or adjacent to the Kaka'ako TOD Overlay project area (Table 1). Several large properties were set aside as crown lands, including the Kulaokahu'a Plains, which include much of the *kula* lands north of King Street (O'Hare and Hammatt 2004:21).

Table 1. LCA Found in and Adjacent to the Kaka'ako TOD Overlay Project Area

I have always understood that this loko descended from Kamehameha I to Kamehameha II and from him to the present King. It was formerly a fish pond but is now a salt pond." (Maly et al. 2013:178; Hammatt 2013: Vol.II,Sec.2, p.51-52)
10811	Hana Puhikakaino	Kawaiahaʻo	No data (Spearing et al. 2008:42)
11212	Kekūanaoʻa, Mataio	Corner of Punchbowl & King Streets	House lot: next to Pahale o Hakau (Jourdane & Dye 2007:6)

Aside from the Māhele'Āina, mid-19th Century events in Kaka'ako and surrounding areas were punctuated by growth in government, missions, epidemics and disease control as well as the reign and subsequent passing of five Hawaiian monarchs.

While the governmental seat had been rooted in Honolulu since the early 19th Century, Honolulu was declared the capitol of the Kingdom of Hawai'i in 1850. The city continued to grow rapidly with large-scale and substantial structures to house documents and the workings of government. By the mid-19th Century, Honolulu contained the royal palace, Honolulu Hale, and court house as well as a fort, battery, three hospitals, and growing system of western infrastructure. Honolulu had also had a growth in commerce, with five markets, forty stores, eight hotels, fifteen victualing houses (restaurants), seven grog shops, three billiard tables, six bowling alleys, forty-seven wholesale and retail suppliers, five wharves, two shipyards, and ten printing offices by the late 1840s (Maly et al. 2013:65-66). As the city expanded, so did the interest in economic development. At this time, much of the coastline was covered in fill to make *'āina hou* (new land), to build more wharves, moorage, and warehouses. The old Pāpū (Fort) at and what was left of Pākākā Heiau were dismantled and/or buried to become a property named the Esplanade, on which the custom house and warehouses were built (Maly et al. 2013:73-74). Salt production also became a major economic force in the mid-19th Century. Figure 8 depicts the configuration of Honolulu in 1843.

In areas outside of Honolulu's capitol, business, residential, and industrial districts, a marked increase in lucrative, non-traditional agriculture occurred, dominated by Western owned sugar and pineapple plantations. Accompanying this was another surge of immigrants, mostly from China and Japan, to work in the plantations. Chinese and Japanese immigrants soon became the most numerous ethnic groups and eventually became land owners. As a result, the need to sustain these populations gave way to another non-traditional agricultural production: rice farming. Most rice farms were owned and operated by Chinese and Japanese (Nakamura 1979).

Figure 8. Charlton's 1843 Annotated Map of Honolulu City (courtesy of Maly et al. 2013:37).

The small pox epidemic of 1853 was one of the most significant events of the 19th Century. Hansen's Disease, also referred to as leprosy, was another malady that plagued Hawai'i at nearly the same time. William Cooper Parke served as Marshal of the Kingdom of Hawai'i from 1850 to 1884, who served under five Hawaiian monarchs during his thirty-four year tenure, and was a member of Kamehameha V's Privy Council. Parke described in his memoirs the great lengths that the Kingdom of Hawai'i went through to prevent and then contain the smallpox epidemic. He describes the chain of events leading up to the epidemic:

> In the month of February, 1853, the ship "Charles Mallory" arrived off the Port with a yellow flag flying from the foremast.
>
> The pilot on going alongside found she had a case of small-pox on board.
>
> The vessel was left outside the port, and the pilot re turned to report the case to the Board of Health. He was ordered to anchor the vessel off Waikiki, where she then was, and the crew with the exception of the sick man were brought on shore, and quarantined in a house that stood near the former residence of Hon. G. W. Macfarlane, at Kapiolani Park.
>
> Here the men were carefully watched and tended by Dr. Hoffman, lest the disease should spread. The sick man was brought to Honolulu, but there was no suitable place to put him.
>
> Prince Lot Kamehameha then offered the use of a house to the Board of Health, which they gladly accepted. This house was a large one, made of grass, in the vicinity of the present Quarantine Station. The house stood on an island, and at high tide was surrounded by water, so that it served the purpose very well.
>
> After taking the patient to the place, and supplying him with what was necessary, no one could be found who was willing to go over and nurse him.
>
> For the first five days he was alone the greater part of the time.
>
> One of the members of the Board went over every morning and prepared the man's food for the day, until he was able to care for himself.
>
> After the vessel had been quarantined for twenty-one days and thoroughly fumigated, she came into port. All the bedding in the forecastle as well as the men's clothing was burned to prevent any further trouble.
>
> After loading with oil the vessel stopped at the Station to take on board the man, who had recovered, and been provided with a new outfit. After the man left the island the house with all its contents was destroyed by fire to prevent any spread of the disease.
>
> As this was the first time such an event had occurred, the Government had no fund from which to defray the expenses of this Quarantine, which amounted to fifteen hundred dollars. I therefore was obliged to pay it myself. […]

> …As no new cases of small-pox appeared for two or three months after the departure of the " Charles Mallory," the authorities felt that they had nothing more to fear in that line; but the one case from that vessel was nothing compared to what followed. On the 13th of May, a man called at my office and reported that two native women living on Maunakea Street were ill, and he feared that the trouble was small-pox. On going to the place the report was found to be true, and a guard was placed around the house, with strict orders to allow no one to leave or enter it. The Legislature was then in session, and on the 16th passed an act authorizing the King, Kamehameha III., to appoint three commissioners of public health ; and on the same day his Majesty nominated Dr. G. P. Judd, Dr. T. C. B. Rooke, and myself… (Parke 1891:49-50).

To follow was a full-scale small pox epidemic that wiped out huge portions of the Native Hawaiian population. Kaka'ako was the location of the temporary quarantines for the disease sufferers as well as Honuakaha Cemetery that accepted its victims.

Despite the tragic outcome of the mid-19th Century epidemics, Honolulu was on the verge of becoming an island metropolis, reminiscent of American cities - only with tropical vegetation by the late 19th Century. Charles Nordhoff, the German-born American journalist, visited Honolulu in the early 1870s and commented on the fair state of the city at that time:

> It is not until you are almost within the harbor that you get a fair view of the city, which lies embowered in palms and fine tamarind-trees, with the tall fronds of the banana peering above the low-roofed houses ; and thus the tropics come after all somewhat suddenly upon you; for the land which you have skirted all the morning is by no means tropical in appearance, and the cocoa-nut groves of Waikiki will disappoint you on their first and too distant view, which gives them the insignificant appearance of tall reeds. But your first view of Honolulu, that from the ship's deck, is one of the pleasantest you can get: it is a view of gray house-tops, hidden in luxuriant green, with a background of volcanic mountains three or four thousand feet high, and an immediate foreground of smooth harbor, gay with man-of-war boats, native canoes and flags, and the wharf, with ladies in carriages, and native fruit-venders in what will seem to you brightly colored night-gowns, eager to sell you a feast of bananas and oranges. […]
>
> From the steamer you proceed to a surprisingly excellent hotel, which was built at a cost of about $120,000, and is owned by the government. You will find it a large building, affording all the conveniences of a first-class hotel in any part of the world. It is built of a concrete stone made on the spot, of which also the new Parliament House is composed; and as it has roomy, well- shaded court-yards and deep, cool piazzas, and breezy halls and good rooms, and baths and gas, and a billiard-room, you might imagine yourself in San Francisco, were it not that you drive in under the shade of cocoa-nut, tamarind, guava, and algeroba trees, and find all the doors and windows open in midwinter; and ladies and children in white sitting on the piazzas. […]
>
> Honolulu, being the capital of the kingdom, contains the government offices; and you will perhaps be surprised, as I was, to find an excellent public hospital, a reform school, and other proper and well-managed charities….if you are

> American, and familiar with New England, it will be revealed to you that the reason why all the country looks so familiar to you is that it is really a very accurate reproduction of New England country scenery. The white frame houses with green blinds, the picket-fences whitewashed until they shine, the stone walls, the small barns, the scanty pastures, the little white frame churches scattered about, the narrow " front yards," the frequent school-houses, usually with but little shade: all New England, genuine and unadulterated; and you have only to eliminate the palms, the bananas, and other tropical vegetation, to have before you a fine bit of Vermont or the stonier parts of Massachusetts. The whole scene has no more breadth nor freedom about it than a petty New England village, but it is just as neat, trim, orderly, and silent also. There is even the same propensity to put all the household affairs under one roof which was born of a severe climate in Massachusetts, but has been brought over to these milder suns by the incorrigible Puritans who founded this bit of civilization (Nordhoff 1874:20-23).

The growth of Honolulu proper rendered the area now referred to as Kaka'ako a suitable place for industry, agriculture, working-class settlements, human and animal quarantine facilities, and ancillary activities. The eastward expansion of Honolulu into the Kaka'ako area is depicted in Figure 9.

In the early 1870s, Curtis Ward, a Kentucky born livery and draying business owner, purchased a total of 89 acres in Kewalo and Kukuluāe'o with 3,000 feet of coastal lands (Thurman et al. 2009:34). This property, located *makai* of Thomas square spanning Kulaokahu'a, Kewalo, and Kukuluāe'o, would soon be known as "The Old Plantation," with nearly 30 irrigated acres of algaroba (*kiawe*) and coconut (O'Hare and Hammatt 2004:25). The Old Plantation also contained a fenced horse pasture, fishponds, taro patches, salt pans, patches of *mānienie* and *makaloa* grass, a hay field, and livestock pens for chicken, pigs, and horses (Thurman et al. 2009:34). After Curtis Ward passed away in 1882, his wife, Victoria, a descendent of *ali'i* and European immigrants, and their seven daughters were left to run the estate for the next fifty years (Spearing et al. 2008:43-44; Thuman et al. 2009:34).

Salt production was certainly not monopolized by the Ward family in late 19th Century Kaka'ako. While the Native Hawaiian tradition of procuring salt from pans and sinks in the area now referred to as Kaka'ako has been practiced from time in memoriam to the mid-19th Century, the commercialization and mass production of salt using foreign methods replaced much of the tradition in the late 19th Century. According to Thrum (1924:116), the salt trade had its peak in 1870 and was nearly extinct by 1883.

Kaka'ako was also associated with the drama being played out in the late 19th Century between mostly Honolulu-based American businessmen and the Hawaiian monarchy, which eventually ended in the demise of the monarchy. The Hawaiian League, a secret society comprised of these American businessmen, was formed to undermine King Kalākaua's government, rendering it a constitutional monarchy headed by the Hawaiian League and Kalākaua as a simple figurehead (Kuykendall 1967:347-352). The Hawaiian League established an unofficial militia, referred to as Honolulu Rifles in 1887, which was based out of Kewalo/Kukuluāe'o. With the added military pressure, Kalākaua buckled and signed a new constitution and

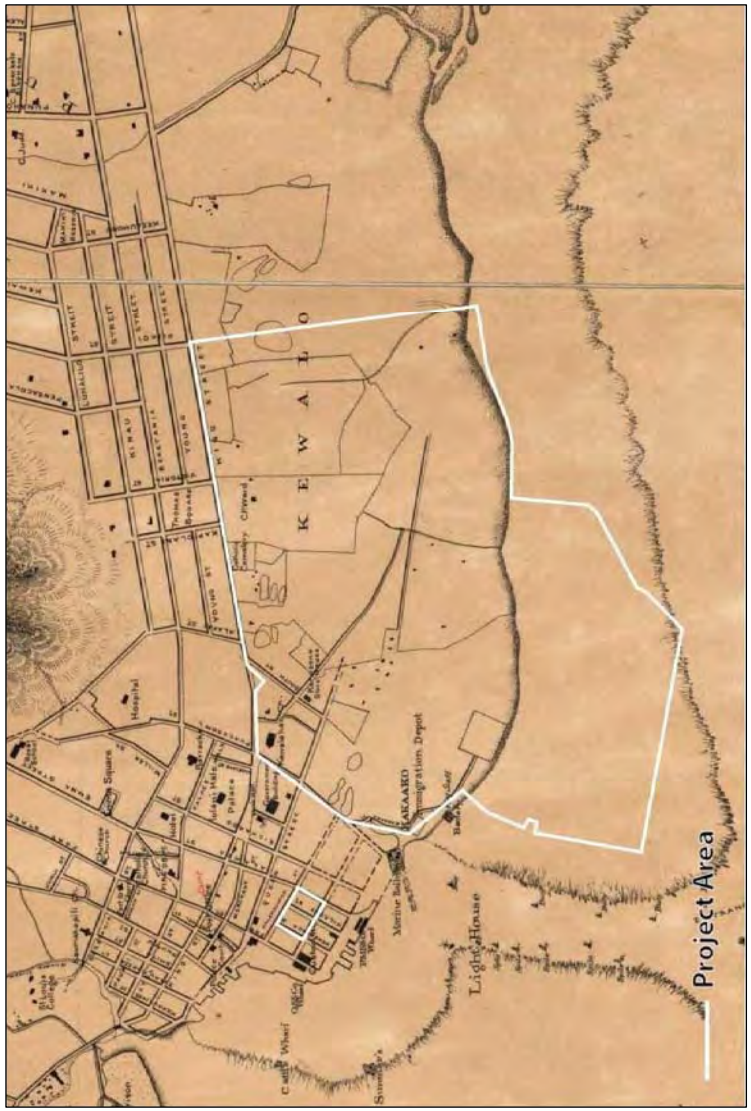

Figure 9. Portion of 1887 Wall Map of Honolulu and Vicinity with approximate project area.

discharged his cabinet, founding the Reform Government. In retaliation to the Hawaiian League's actions, supporters of the monarchy, made largely of Hawaiians and part Hawaiians, banded together to form the Kamehameha Rifle Association. Despite their efforts, the monarchy fell to the founders of the Hawaiian League.

3.2.3 Kaka'ako in the 20th Century

Kaka'ako continued to change drastically after turn-of-the-Century following the annexation of the islands in 1899 by the United States. Early 19th Century events in Kaka'ako and surrounding areas were marked by the spread of tenement housing, industry, and infrastructure as well as development on "reclaimed lands" along the coast.

As Honolulu expanded, demand for affordable housing increased, which was partially driven by the exodus of people fleeing the bubonic plague that broke out in Chinatown. To control the outbreak of bubonic plague, the tenements of Chinatown were destroyed by "controlled burning." After several successful controlled burns, the burn of 20 January 1900 was blown off the prescribe burn area, unintentionally burning 38 acres of homes and businesses and displacing nearly 6,000 Hawaiian, Japanese, and Chinese. Many of the displaced rebuilt in Chinatown, but the majority settled in tenements built by Bishop, Magoon, and Ward Estates. Joining those relocating from Chinatown were Hawaiians from rural areas and families leaving the plantations for work in Kaka'ako's industrial district, coastal fishing industries, and civic or business jobs in Honolulu. Typically, these new Kaka'ako neighborhoods were ethnically segregated out of convenience and comfort, yet socializing and commerce continued between the ethnic communities (McGregor 1989). By 1940, over 5,000 people of Hawaiian, Portuguese, Chinese, Japanese, and Filipino descent were living in Kaka'ako (Spearing et al. 2008).

However, because these tenements were built with such haste, the communities were not well planned, in terms of health and safety, and structures were substandard. As a result, a cholera outbreak occurred in 1911 as well as a trend of physical and mental deficiencies in Kaka'ako's children. Further, structures quickly became dilapidated and unfit for habitation (McGregor 1989). For a short period, many Hawaiians from Kaka'ako resettled in coastal "squatter" camps; living off the land and ocean much as their ancestors did.

Small industry was also on the rise in early 20th Century Kaka'ako, including fish processing and canning iron works, *poi* processing, flour milling, beer brewing, and brick production. According to McGreggor (1989), the population of Kaka'ako's 600 acres was over 2,500. Small businesses, such as grocery stores, restaurants, meat markets, barber shops, theatres, and specialty shops were established as the neighborhoods grew. Schools, public parks, fire and police stations, municipal buildings, a public landfill and incinerator, animal quarantine and shelter, and improved roadways also followed. In addition to commercial developments, the U.S. military installation, Fort Armstrong, was constructed on the reef of Ka'ākaukukui as part of the Coastal Defense System after the annexation of the islands by the United States in 1899 (Spearing et al. 2008: 52).

In the early 19th Century, the coast and wetlands of Kaka'ako and Waikīkī underwent dramatic changes as well. The "Reclamation" Project was, perhaps, the most transformative event in the area's history. On the face of it, the project was an undertaking to fill in mostly agricultural

ponds and wetlands that were supposedly compromising public health by acting as a breeding ground for disease bearing mosquitoes. However, according to Nakamura (1979), this project served to generate capital for Hawaiian construction companies while increasing residential land and land value as well as gentrifying the area by forcing out farmers and underprivileged families. This decade-long project not only transformed the coastlines of Kaka'ako and Waikīkī, but altered the ecology and cultural landscape forever. While most of the coast was extended makai, Kewalo Basin was dredged to expand the small harbor for the lumber industry, which soon gave way for the fishing industry (Spearing et al. 2008).

3.3 The Archaeological Record

Several cultural and archaeological studies performed within and adjacent to the Kaka'ako TOD Overlay project area have compiled all archaeological investigations and findings for this area (O'Hare and Hammatt 2004; Spearing et al. 2008; Thurman et al. 2009; Genz and Hammatt 2010; Vogeler et al. 2010; Hammatt 2013). Based on the above reports, a total of 87 archaeological investigations have been performed within or adjacent to the project area. A total of 48 new archaeological sites were discovered in these investigations. Human remains, including pre-and post Contact Native Hawaiian burials as well as Historic era non-Hawaiian burials, have been ubiquitous throughout the project area, totaling nearly 500 individuals (MNI=493) between all previous archaeological investigations. Maps for all archaeological investigations, archaeological sites, and human burials can be found in each respective report and are provided in Appendix C. Table 2 provides a list of archaeological investigations performed in the project area as well as archaeological sites found during these investigations based upon O'Hare and Hammatt (2004), Spearing et al. (2008), Genz and Hammatt (2010), Vogeler et al. (2010), Elison and McElroy (2011), and Hammatt (2013).

Table 2. Previous Archaeological Work in the Kaka'ako TOD Overlay Project Area

Author	SIHP No. 50-80-14	No. of Burials	Report Description and Findings
Pearson 1980, 1995	-9991		Test pits were excavated near the Mission Houses (-9991); 19th and 20th century artifacts were recovered.
Ota & Kam 1982	-2963	6	Osteological Study, Makai Parking Garage, corner of Punchbowl and Halekauwila Streets (TMK 2-1-31:23) - Six partial burial sets (SIHP #50-80-14-2963) found. Tooth evulsion indicates probable pre-Contact to 1850 date.
Yent 1985	-2918	5	Ka'ākaukukui Cemetery (-2918) at the Honolulu Iron Works project area - Five burials (SIHP #50-80-14- 2918) recorded
Athens 1986	-1973		Monitoring of Judiciary Parking Lot - Historic deposits (SIHP #50-80-14-1973) with artifacts dating late nineteenth to early twentieth centuries
Clark 1987	-2963	7	Archaeological monitoring at Makai Parking Garage, corner of Punchbowl and Halekauwila Streets (TMK 2-1-31:23) - One cultural resource identified: SIHP #50-80-14-2963; seven burials probably dating to pre -1850
Griffin et al. 1987	-2918	3	Background research and predictive models; reports on an additional 3 burials at Ka'ākaukukui Cemetery (-2918).

Author	SIHP No. 50-80-14	No. of Burials	Report Description and Findings
Davis et al. 1988			During monitoring at the Honolulu Iron Works site, no additional human burials were found in the area surrounding Kaʻākaukukui Cemetery (site -2918).
Leidemann 1988	-1973		Monitoring at Federal Building parking lot - Historic deposits (SIHP #50-80-14-1973) found
Smith 1989	-4243	1	Kamakeʻe to Keʻeaumoku – one human bone found
Bordner 1990	-9991		Test trenches were excavated in the Kawaiahaʻo Church grounds (-9991); Some historic artifacts were recovered.
Douglas 1991a	-4380	8	Coral and Queen Street area: 8 burials (-4380) recorded and 5 disinterred.
Douglas 1991b	-4380	1	Coral and Queen Street area: 1 burial recorded (-4380).
Kawachi 1991	-1604	2	Monitoring at the Queen Emmalina Tower project; 1 human skull and 1 femur (-1604) were found in the back dirt pile
Schilz 1991	-1604	2	Background research and property assessment of Queen Emmalina Tower project, a block formerly used for kerosene storage and for tenements (Magoon Block); in subsequent projects, human remains were found and designated site -1604.
Chiogioji & Hammatt 1992	N/A		Archaeological background research and brief surface field inspection at former lot of Kapiʻolani Community College adjacent to McKinley High School (site -9926). No findings.
Avery & Kennedy 1993a	-3712	3	Monitoring at 1853-1854 Honuakaha Smallpox Cemetery; 3 historic burials recorded.
Avery & Kennedy 1993b	-3712	6	Monitoring of South St. Building Complex, 6 burials associated with 1853-1854 Honuakaha Smallpox Cemetery were found.
Denham & Kennedy 1993	-4605 -4606	1	Archaeological monitoring for the State Capitol Complex Telecommunications Conduits Project documented two cultural resources: SIHP #50-80-14-4606, a multi-component site consisting of a human burial, historic trash pit, firepit, and 6 postholes, and SIHP #50-80-14-4606 consisting of 9 historic trash pits
Hammatt 1993	-3712 -9917	31	Subsurface Inventory Survey; found 31 burial pits from the1853 -1854 Honuakaha Smallpox Cemetery (-3712) and 3 refuse pits associated with the Honolulu Brewing Co. (-9917)
Hammatt and Pfeffer 1993	-3712	29	Archaeological inventory survey at the American Brewery lot – identified 29 burial pits associated with the Honuakaha Cemetery (SIHP #50-80-14-3712) and 3 refuse pits associated with the brewery
Miyasaki and Ogata 1993	-9917		Environmental site assessment of the American Brewery Co. building (site -9917). No field work.
Pfeffer, Borthwick, & Hammatt 1993	-3712 -4531 -4532 -4533 -4534	31 1 1 116	Monitoring for Kakaʻako ID-1 - 31 burials from 1853-1854 Honuakaha Smallpox Cemetery (SIHP #50-80-14-3712/-4531) at Quinn Lane; one historic burial from Punchbowl St. (SIHP #50-80-14-4532); one possibly pre-Contact burial from Halekauwila St. (SIHP #50-80-14-4533); and 116 historic burials from Kawaiahaʻo Cemetery (SIHP #50-80-14-4534) at Queen St. (used from 1825-1920)

Author	SIHP No. 50-80-14	No. of Burials	Report Description and Findings
Athens et al. 1994	-4847	1	Wetland environment on Kapi'olani and Pi'ikoi Sts.; 1 human burial (-4847) recorded.
Heidel & Hammatt 1994	-1346		Background research on the Kakaʻako Fire Station building and lot (-1346). No field work.
Anderson 1995, 1997a, 1997b	-5373	30	Three reports on One Archer Lane project area (inventory survey, monitoring and burial disinterment); minimum of 30 historic human burials (-5373) recorded along western side of the Roman Catholic Cemetery on King St.
Hammatt & Chiogioji 1995	N/A		Archaeological assessment of 20 parcels and background research; No field work conducted.
Kapeliela 1996	-5455	1	Burial find; 1 historic human burial (-5455) found on west side of Roman Catholic Church on King St.
Winieski et al. 1996	-3712	25	Archaeological monitoring as well as disinterment of 25 sets of human remains (SIHP #50-80-14-3712) at the Honuakaha Housing Project (Honolulu Brewery site). Monitoring documented historic artifacts ranging from the 1880s to the turn of the 20th century. Eleven previously identified and 14 inadvertent find of human remains were disinterred and reinterred on the property.
Allen 1997	N/A		Monitoring of geotechnical coring in Symphony Park; no site designations made.
Hammatt & Chiogioji 1998	-1388		Archaeological Assessment of area that includes Mother Waldron Neighborhood Park playground (-1388) and Pohukaina Elementary School. No field work.
Sinoto2000	N/A		Wal-Mart/Sam's Club Development Area: Archaeological Assessment with recommendation for Archaeological Monitoring
Winieski & Hammatt 2000a	-1388 -4380 -5820	9 11	Archaeological monitoring at the Kakaʻako Improvement District 3 area - 20 human burials were encountered. Nine burials were discovered at the Pohulani Elderly Rental Housing (SIHP #50-80-14-4380), and 11 were in and around Mother Waldron Neighborhood Park (SIHP #50-80-14-5820).
Winieski & Hammatt 2000b	-5598	2	Monitoring for Kakaʻako Improvement District 4 construction - Two isolated historic coffin burials (SIHP #50-80-14-5598) were documented on Kamakeʻe Street, between the intersections of Kawaiahaʻo and Waimanu Streets.
Winieski & Hammatt 2001a	-5942		Archaeological monitoring along Nimitz Highway, Queen Street, and Ala Moana Boulevard which documented historic trash within fill, a brick alignment, a brick lined manhole, and the remains of a light gauge rail associated with the historic Honolulu Rapid Transit System, SIHP #50-80-14-5942
Winieski & Hammatt 2001b	N/A		Archaeological monitoring of boring at the Kakaʻako Fire Station. No cultural material or human remains were observed.
Winieski & Hammatt 2001c	N/A		Archaeological monitoring at the Ward Village Phase II project (Ward Theatres documented pockets of a sandy loam buried A-horizon – no archaeological cultural resources were identified
Bush & Hammatt 2002	N/A		Kakaʻako ID-10: Monitoring Plan

Author	SIHP No. 50-80-14	No. of Burials	Report Description and Findings
Mann & Hammatt 2002	-6371	1	Monitoring for King St. Alignment; 1 burial (-6731) found, possibly post-Contact due to presence of historic artifact.
Sinoto & Pantaleo 2002	N/A		Wal-Mart/Sam's Club Development Area: Monitoring Plan
Souza, Perzinski, & Hammatt 2002	-6376 -6377 -6378		Kaka'ako Improvement District 7 Monitoring - Three burials encountered: SIHP #50-80-14-6376, SIHP #50-80-14-6377, and SIHP #50-80-14-6378
O'Hare et al. 2003	-6636 -6637		Inventory survey at the corner of Pi'ikoi St. and Kapi'olani Blvd. – documented 4 features consisting of 2 historic trash pits, a pit containing ceramic insulators, and an artificially constructed sand berm with a possible coral retaining wall and a wooden fence post. The sand berm feature was designated part of SIHP #50-80-14-6636. one historic trash pit (site-6637) reported.
Le Suer and Cleghorn 2004	N/A		Archaeological assessment (no fieldwork) for East O'ahu Transmission Project; King St.
O'Hare et al. 2004	-6636 -6639 -6641		Archaeological inventory survey for the Ko'olani Condominium Project; Original wetland surface of Kewalo (-site 6636) and three historic trash pits (sites -6639, -6641) reported.
O'Hare, Bush, Borthwick, & Hammatt 2004	-6639 -6641 -6636		Inventory survey Ko'olani Condominium – Three cultural resources documented: SIHP #50-80-14-6639 and SIHP #50-80-14-6641, historic trash pits dating from the early twentieth century; and SIHP #50-80-14- 6636, the original wetland surface of Kewalo
O'Leary & Hammatt 2004	N/A		Monitoring for Unit 9 streets; no cultural remains found.
Perzinski & Hammatt 2004	N/A		Monitoring of geotechnical borings at the Kaka'ako Fire Station, no cultural material was found in 12 test trenches.
Clark & Gosser 2005	-6636		Subsurface inventory survey of TMK 2-3-003:075, 085, 086. Previously described wetland area recorded (-6636).
Cordy and Hammatt 2005	N/A		Archaeological monitoring Punchbowl St. - No historic properties identified; observed stratigraphy generally consisted of historic and modern fill material overlying naturally deposited sediment layers (Jaucas sand or black cinder).
Monahan 2005	N/A		Assessment of three parcels in Kewalo; no cultural materials found in nine trenches.
Tulchin, T. & Hammatt 2005	-6636 -6641		Inventory survey Phase II portion of the Ko'olani Condominium parcel - Two cultural resources identified: SIHP #50-80-14-6636, original wetland surface of Kewalo area; and SIHP #50-80-14-6641, historic garbage layer—both previously identified by O'Hare et al. (2004)

Author	SIHP No. 50-80-14	No. of Burials	Report Description and Findings
Bell et al. 2006	-6854 -6855 -6856	5 6	Archaeological inventory survey for Victoria Ward Village Shops – Three cultural resources identified: SIHP #50-80-14-6854, subsurface cultural layer containing both historic and prehistoric cultural material and five human burials; SIHP #50-80-14-6855, pre-Contact traditional Hawaiian cultural layer with six human burials; and SIHP #50-80-14-6856, historic fishpond remnant
Bush & Hammatt 2006	N/A		Monitoring for Hokua Tower Project; no cultural remains found.
Esh & Hammatt 2006	N/A		Monitoring of Unit 5 B Streets; no cultural materials found.
Gosser et al. 2006	N/A		Monitoring at the corner of Kapi'olani Blvd. and Kamake'e St. documented no finds
Hammatt 2006a	N/A		Kapi'olani Blvd. field inspection; no surface historic properties were observed
Hammatt 2006b	-6847		Archaeological inventory survey; one feature, a wooden box containing historic artifacts (Site - 6847)
O'Hare et al. 2006	-6658 -6659 -6660	28 2	Queen Street Extension Project; monitoring at Kaka'ako ID-10; cluster of 28 historic burials (-6658), 2 isolated burials (-6659), and a historic trash dump (-6660) were recorded.
O'Leary & Hammatt 2006	N/A		Archaeological inventory survey for the Moana Vista project area; no cultural materials found.
Perzinski et al. 2006	-5455	2	Kewalo HECO Dispatch Center 6 trenches and 9 pile caps excavated; 2 human burials recorded (Site -5455)
Barnes & Shideler 2007	N/A		No surface features found during a field inspection. Background research indicated the possibility of subsurface burials
Hammatt 2007	-6910 -6911 -6912	16 2	Monitoring at Ko'olani Condominium; 2 isolated burials (-6910, -6912) and cluster of 16 coffin burials (-6911) found.
Hazlett et al. 2007a	-1604	2	Monitoring at Queen Emmalani project; 2 human skeletal elements found and recorded as part of site -1604.
Hazlett et al. 2007b	-6637		Monitoring at Moana Pacific property; historic deposit recorded (-6637).
O'Hare et al. 2007	-6901 -6902	3	Alapai Transit Center 28 trenches excavated; 4 trash pits (Site -6901) and 3 burials (Site -6902) discovered
Stein et al. 2007	N/A		Monitoring for the Kaka'ako Fire Station renovation – no cultural resources were identified
Carney and Hammatt 2008	-6765	1	Archaeological monitoring of the Hokua Tower Project which identified 2 historic properties: SIHP #50-80-14-6765, an isolated fragment of a human mandible, and a historic trash pit
Hammatt 2008	-6910 -6911 -6912		Monitoring associated with the development of the Ko'olani Towers Phase I - Three cultural resources identified: SIHP #50-80-14-6910, a single pre-Contact burial; SIHP #50-80-14-6911, a cluster of 16 historic coffin burials; and SIHP #50-80-14-6912, a single burial

Author	SIHP No. 50-80-14	No. of Burials	Report Description and Findings
Hazlett and Hammatt 2008	N/A		Archaeological monitoring at the intersections of Alakea and Merchant Streets and Alakea and Queen Streets. No historic properties were identified.
Hazlett, Fehrenbach, and Hammatt 2008	N/A		Archaeological monitoring for water main installation on Aloha Tower Drive - no cultural resources were encountered during project construction; observed stratigraphy consisted entirely of fill associated with modern road and utility construction, as well as historic land filling activities, associated with the expansion of Honolulu Harbor.
Hazlett, Loynaz, and McDermott 2008	N/A		Monitoring of the Ala Moana expansion project - No historic properties encountered
Petrey et al. 2009	N/A		Archaeological monitoring for resurfacing of portions of Nimitz Highway and Ala Moana Boulevard, installation of streetlights, replacement of concrete bus pads, and limited drainage installation. No archaeological cultural resources were documented.
Fong, Borthwick, & Hammatt 2009	N/A		Monitoring of Kapi‘olani Boulevard Drainage, Water, and Sewer Systems Improvements - No cultural resources observed
O’Hare, Tulchin, T., Borthwick, & Hammatt 2009	N/A		Archaeological inventory survey plan for three Kamehameha Schools Kaka‘ako Mauka parcels including Civic Center Transit Center location - Preliminary testing identified extensive fill layers overlying naturally deposited sandy clay and marsh/pond sediments. No cultural resources identified
Pammer et al. 2009	-6901		Alapai Transit Center 15 test trenches excavated; 3 additional historic trash pits observed (Site -6901)
Thurman, Altizer, O’Hare, Shideler, & Hammatt 2009	-6856		Archaeological inventory survey for Queen Street parks project - One previously identified cultural resources: SIHP #50-80-14-6856, a historic fishpond remnant, originally identified by Bell et al. (2006)
Tulchin, T. Altizer, Borthwick, & Hammatt 2009	N/A		Archaeological assessment of the proposed Halekauwila Place Project - No cultural resources identified. The stratigraphy observed within the subject parcel generally consisted of three to five layers of historic and modern fill material overlying naturally deposited sediment layers (sandy clay and gleyed clay sediments typical of a wet, marsh-type environment).
McElroy 2010	-6516 -6661 -6662	64	This after-the-fact archaeological monitoring report documents human remains (MNI = 64) found in six areas, assigned SIHP #s 50-80-14-6516, -6661, and -6662. Both pre-Contact and post-Contact burials
Pammer & Hammatt 2010a	N/A		Archaeological assessment - No cultural resources were identified within the 4.7-acre project area. The project area was observed to have undergone extensive land modification by the filling of the low lying areas of Kaka‘ako.
Pammer & Hammatt 2010b	N/A		Archaeological assessment for an approximately 0.26-acre Moana Vista project on Kapi‘olani Boulevard - No cultural resources identified

Author	SIHP No. 50-80-14	No. of Burials	Report Description and Findings
Altizer et al. 2011	-6636		This archaeological monitoring report for the Kapi‘olani area revised sewer system documented SIHP #50-30-14-6636, a wetland deposit, in Sewer Line G, near Kamaile Street, far from the present project area.
Pammer, Fong, & Hammatt 2011	-7124 -7189 -7190 -7197		A total of four cultural resources were identified within the project area: SIHP #50-80-14-7124, -7189, -7190 and -7197. SIHP #50-80-14-7124 consists of 31 historic building remnants features (Features A – EE), generally located just beneath the modern layers of fill. SIHP #50-80-14-7189 consists of a layer of burnt historic debris, suspected to be from the open air burning of urban refuse during the early 1900s. SIHP #50-80-14-7190 consists of old salt pan remnants, presenting as an approximately 5 cm thick layer of alternating peat and clay striations. SIHP #50-80-14-7197 consists of a sandy cultural layer containing one late pre-Contact/early post-Contact fire pit feature.
Runyon, Thurman, O’Hare, Borthwick, & Hammatt 2011	-6636 -6641 -7115 -7116 -7117	27	Five cultural resources are significant based on Hawai‘i Register* criteria: SIHP #50-80-14-6641, a burnt historic trash layer, was previously evaluated and determined significant under criteria A and D; SIHP #50-80-14-6636, Kewalo wetland sediment, was previously evaluated and determined significant under criteria A and D; SIHP #50-80-14-7115, a subsurface cultural layer containing intact pit features and artifacts is significant based on criteria A, D, and E; SIHP #50-80-14-7116, a buried low-energy alluvial layer, is significant based on criteria A and D; SIHP #50-80-14–7117, based on available archaeological information, is a concentration of post-Contact human burials, the majority of which are in an extended burial posture and located in coffins. All 27 burials were documented in pits extending down from the overlying buried, culturally-enriched A-horizon (SIHP #-7115).
Yamauchi et al. 2011	N/A		Archaeological monitoring for the Queen and Kamake‘e traffic signal project - no cultural resources were identified
Burke and Hammatt 2012	7193		1391 Kapi‘olani Boulevard Parcel - archaeological inventory survey for a 1391 Kapi‘olani Boulevard parcel involving 22 test excavations. SIHP #50-80-14-7193, a historic trash layer dating from the 1930s to the 1950s, was documented.
Runyon, Borthwick, and Hammatt 2012	-6636		Archaeological Inventory Survey Report for the Senior Residence at Pi‘ikoi. SIHP #50-80-14-6636 consists of buried Kewalo wetland sediments, found in all test trenches in the project area. The site has been previously documented in nearby areas in Kaka‘ako (O’Hare et al. 2003, O’Hare et al. 2004, Tulchin, T. and Hammatt 2005, and Runyon et al. 2011).
Sroat and McDermott 2012	-6855		This supplemental archaeological inventory survey report for the Ward Village Shops Phase 2 project identified no new cultural resources. Further documentation of SIHP 50-80-14-6855 was conducted
Dagher and Spear 2013 (draft)	-7260	1	This burial site component of a data recovery plan for State Site 50-890-14-7260 addresses the inadvertent find of a partial set of displaced human skeletal remains at the east corner of Halekauwila Street and Cooke Street.
Morriss, Hunkin, and McDermott 2013 (draft)	-6636		Archaeological inventory survey for the Ala Moana Center ‘Ewa Mall Expansion Project. Identified SIHP #50-80-14-6636, buried Kewalo wetland sediments, and possible salt pan remnants (however further investigation was deemed necessary to confirm).

3.4 IWI KŪPUNA

The Kaka'ako TOD Overlay project area is situated in a region that has a relatively high human burial density, with a total of nearly 500 individuals encountered by inadvertent discovery (MNI=493; Table 2). *Iwi kūpuna* are the ancestral skeletal remains of Native Hawaiians. Yet, the term may be applied to the ancestral remains of non-Hawaiians that are also found in Kaka'ako, such as those who perished in the Historic era small pox epidemic. These remains are highly revered by contemporary Hawaiians and other individuals share these beliefs. In the Native Hawaiaan belief system, it is largely believed that, upon death, the *nā iwi* of a person become the repository of the *mana* (power, authority) they possessed in life. The method of traditional Hawaiian burials varied with an individual's social status as well as the customs of the area that they lived and constraints dictated by the area's topography and soil makeup. Coastal properties, especially where there are areas of sand, were common grounds for Native Hawaiian burials. Traditionally, the *kuleana* (responsibility, privilege) of caring for *nā iwi* was a sacred task. In general, Native Hawaiians strongly believe that *iwi kūpuna* should not be disturbed and rest in the original place of burial.

The proper treatment of *iwi kūpuna* has not always been enforced, as a Burial Treatment Plan (BTP) was not required by law until the late 1980s, and the treatment of *iwi kūpuna* was discretionary until that time. Traditionally, the *kuleana* (responsibility) to *mālama* (take care of) the *iwi kūpuna* was in the hands of the descendents and/or the *konohiki*. In accord with these traditional values, burial councils were formed for every island in the state. The O'ahu Island Burial Council (OIBC), which meets once a month, is comprised of community members appointed by the Governor of Hawai'i and confirmed by the Senate to serve a four-year term. No member can serve more than two consecutive terms. According to the Department of Land and Natural Resources (DLNR) Burial Sites Program, the rules regarding inadvertent discoveries are summarized as follows:

> Anyone who wishes to relocate, or preserve in place, previously identified, Hawaiian burials over 50 years old must obtain the approval of the appropriate Island Burial Council, which meets on a monthly basis on its respective islands.
>
> Any skeletal remains accidentally discovered must be reported to the Historic Preservation Division and County police. If burial remains are estimated to be less than 50 years old, they fall under the jurisdiction of the local police.
>
> The division currently responds to approximately 2-3 inadvertent discoveries each week, and is involved in up to 250 burial cases annually. Since 1991, approximately 3,000 sets of native Hawaiian skeletal remains have been re-interred thanks to the collaborative efforts of the division, various Hawaiian organizations, and property owners (DLNR 2013).

As the Kaka'ako area is known to have a high density *of iwi kūpuna* and the human remains of other ethnic groups, conscientiousness to this fact in planning development in the area is crucial. Proper preventative measures, such as thorough cultural and archaeological investigations, should be employed prior to planning developments in the area. Further, inadvertent discovery protocols must be strictly followed by developers.

It is important to note that despite the fact that pre-Contact and Historic era human burials are ubiquitous in Kaka'ako, the potential for encountering iwi kūpuna dramatically decreases for "reclaimed" lands that were essentially under water prior to European Contact. Figure 10 provides a NRCS based soil map of the project area with estimated original shoreline as indicated on Historic maps (still adding maps).

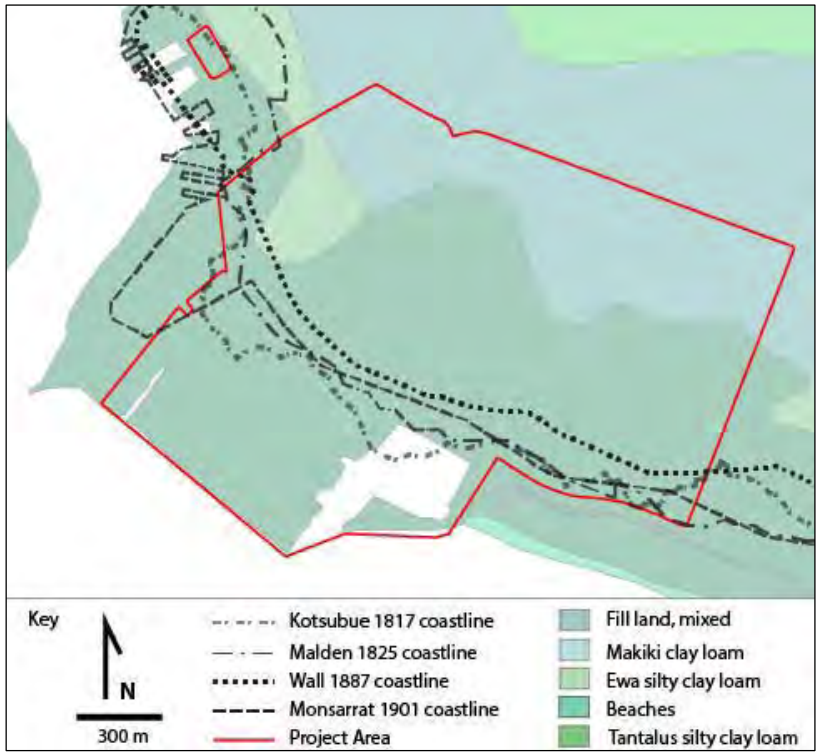

Figure 10. Map Af Kaka'Ako Soils with Historic Map Coastline Depictions Overlayed.

4.0 PREVIOUSLY PERFORMED CULTURAL STUDIES FOR KAKA'AKO

This review focuses on two ethno-historical investigations, five CIA, and one Traditional Cultural Property (TCP) study that were performed within the Kaka'ako TOD Overlay project area. The subject area consists of KCDD lands comprised of 601.6 acres bounded by King Street to the north, Pi'ikoi Street to the east, Ala Moana to the southeast, Māmala Bay to the south, Pier 1 to the southwest, and Punchbowl Street to the west, as well as the Aloha Tower Special District comprised of 3.4 acres bounded by South Nimitz Highway to the north, Richard Street to the east, Aloha Tower Drive to the south, and Bishop Street to the west (Figure 1).

4.1 PREVIOUS ETHNO-HISTORICAL INVESTIGATIONS

Two ethno-historical investigations were performed for areas that incorporate the current project area (University of Hawai'i 1978; McElroy et al. 2008).

4.1.1University of Hawai'i Ethnic Studies Department Oral History Project

In 1978, the University of Hawai'i published a two-volume ethnographic study for the Kaka'ako area, titled: *Remembering Kaka'ako, 1910-1950* (University of Hawai'i 1978). In reaction to the increased development of Kaka'ako, 29 individuals hailing from Kaka'ako were interviewed to elucidate what life was like from the early to mid-20th Century for its inhabitants. Interviewees represented a broad cross-section of Kaka'ako who were ethnically diverse and predominantly working class. The general finding from this study was that the Kaka'ako of the interviewees' memories was rapidly disappearing as residential areas became urban and industrial (Spearing et al. 2008).

4.1.2 Kamehameha Schools Ethno-Historical Inventory Study

An Ethno-Historical Inventory Study was performed in 2008 by Garcia and Associates for 47 parcels on 51.3 acres in Kaka'ako owned by Kamehameha Schools (McElroy et al. 2008). This study included four interviews with long-time Kaka'ako community members as well as a compilation of Historic maps, photographs, Hawaiian and English news articles, and other archival materials. Spearing et al. (2008:69-72) provides numerous excerpts from the McElroy et al. (2008) report that relate to the Kaka'ako Mauka area. The findings of McElroy et al. (2008) echoed those of the University of Hawai'i (1978), where Kaka'ako had dramatically changed from a fishing village to the metropolis we currently recognize (McElroy et al. 2008). Further, the interviews resulted in diminutive information on traditional Native Hawaiian cultural practices in the area or *mo'olelo* regarding Kaka'ako (McElroy et al. 2008).

4.2 PREVIOUS CULTURAL IMPACT ASSESSMENTS

Between 2002 and 2011, several CIAs in the Kaka'ako TOD Overlay project area were conducted. Much of the subject area was covered in the previously conducted CIAs. Therefore, a Supplemental CIA (SCIA) was determined to sufficiently assess cultural impacts for the Kaka'ako area. Five CIAs covering the Kaka'ako TOD project area were reviewed for the SCIA consist of:

- Wilson Okamoto and Associates, Inc.
  2002 Cultural Impact Assessment in the Final Environmental Assessment University of Hawaii Health and Wellness Center. Prepared for the University of Hawaii, John A. Burns School of Medicine. Prepared by Wilson Okamoto and Associates, Inc.

- Spearing, Mishalla, Constance O'Hare, and Hallett H. Hammatt
  2008 Cultural Impact Assessment for the Kaka'ako Community Development District Mauka Area Plan, Waikīkī Ahupua'a, Honolulu (Kona) District, O'ahu Island. TMK: [1] 2-1-29-32, 44, 46-56 and 2-3-01-11. Prepared by Cultural Surveys Hawai'i, Inc.

- Vogeler, Kuhio, Lehua Kauhane, and Hallet H. Hammatt
  2010 Cultural Impact Assessment for the Proposed McKinley High School Athletic Complex Master Plan Project, Honolulu (Kewalo) Ahupua'a, Honolulu District (Kona Moku), Island of O'ahu. TMK: [1] 2-3-009:001 por. Prepared by Cultural Surveys Hawai'i, Inc.

- Genz, Joseph H. and Hallett H. Hammatt
  2010 Cultural Impact Assessment for the Kewalo Basin Repairs Project, Kaka'ako Ahupua'a, Honolulu (Kona District), O'ahu. TMK: [1] 2-1-058. Prepared by Cultural Surveys Hawai'i, Inc.

- Elison, Mina and Windy K. McElroy
  2011 Final – Cultural Impact Assessment for Kaka'ako, Ahupua'a of Waikīkī, Kona District, Island of O'ahu, Hawai'i. TMK: [1] 2-3-006:017. Prepared by Keala Pono Archaeological Consulting, LLC.

The project area covered by Wilson Okamoto and Associates, Inc. (2002) is on two parcels, totaling 9.9 acres, bound by Kaka'ako Waterfront Park to the south, Ilalo Street to the north, Fort Armstrong Street to the west, and Cooke Street and Kaka'ako Makai Gateway Park to the east (Figure 11). Spearing et al. (2008) covers The Kaka'ako Community Development District Mauka Area, which is bound by King Street to the north, Pi'ikoi Street to the east, Ala Moana Boulevard to the South, and Punchbowl Street to the south (Figure 12). The project area covered by Vogeler et al. (2010:17) "…is a portion of the present McKinley High School campus, located north-east of Kapi'olani Boulevard and between the Neal Blaisdell Exhibition Center on the west and Pensacola Street on the east" (Figure 13). While the CIA prepared for McKinley High School (Vogeler et al. 2010) was focused on a property within the Kaka'ako Community Development District Mauka Area, which is the subject location for the CIA prepared by Spearing et al. (2008), additional cultural resources were identified by Spearing et al. (2008), as it was conducted more recently. Thus, both will be included in this review. The Genz and Hammatt (2010) CIA focuses on the Kewalo Basin, which is comprised of 22 marine acres of the mixed-use harbor, including the immediately adjacent "reclaimed " lands (Figure 14). Elison and McElroy (2011) covers the 1.73 acre parcel bound by Waimanu Street to the north, Pi'ikoi Street to the east, Ala Moana Boulevard to the south, and Kamake'e Street to the west (Figure 15).

Figure 11. 1998 Honolulu Quadrangle U.S. Geological Survey 7.5-minute topographic map showing Wilson Okamoto and Associates, Inc. project area location.

Figure 12. 1998 Honolulu Quadrangle USGS 7.5-minute topographic map depicting Kaka'ako Community Development Mauka Area District (Spearing et al. 2008: Figure 1).

Figure 13. 1998 Honolulu Quadrangle U.S. Geological Survey 7.5-minute topographic map showing project area location (Vogeler et al. 2010: Figure 1).

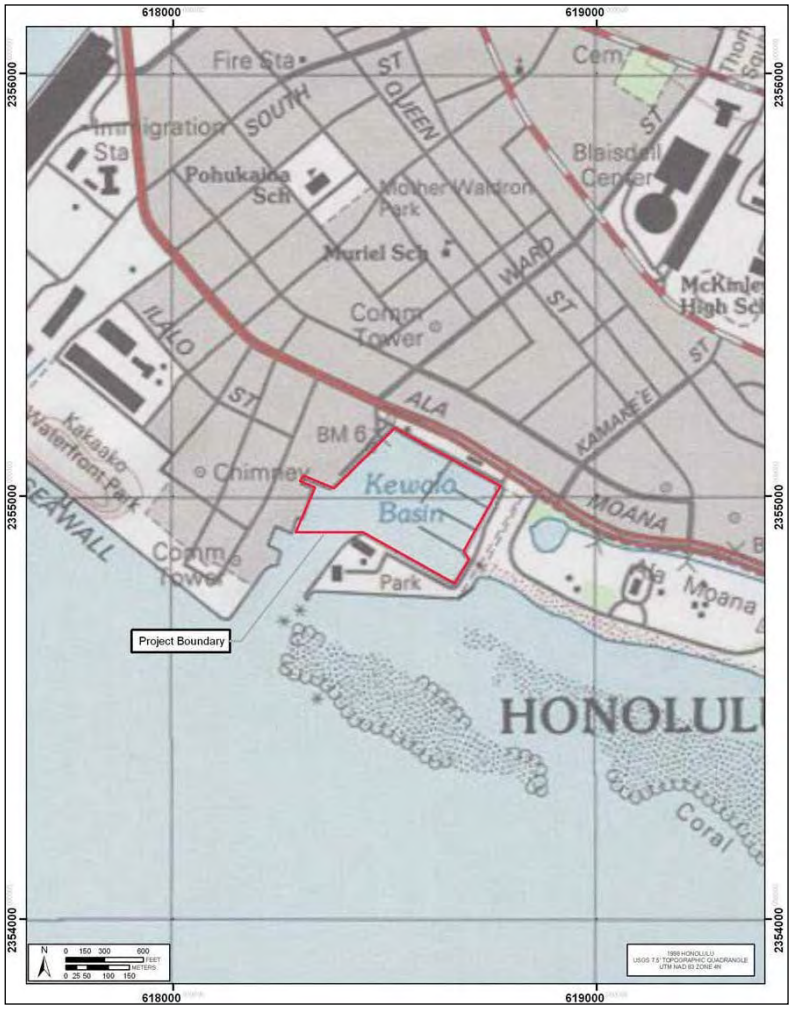

Figure 14. 1998 Honolulu Quadrangle USGS 7.5-minute topographic map depicting Kewalo Basin Repairs Project Area (Genz & Hammatt 2010: Figure 3).

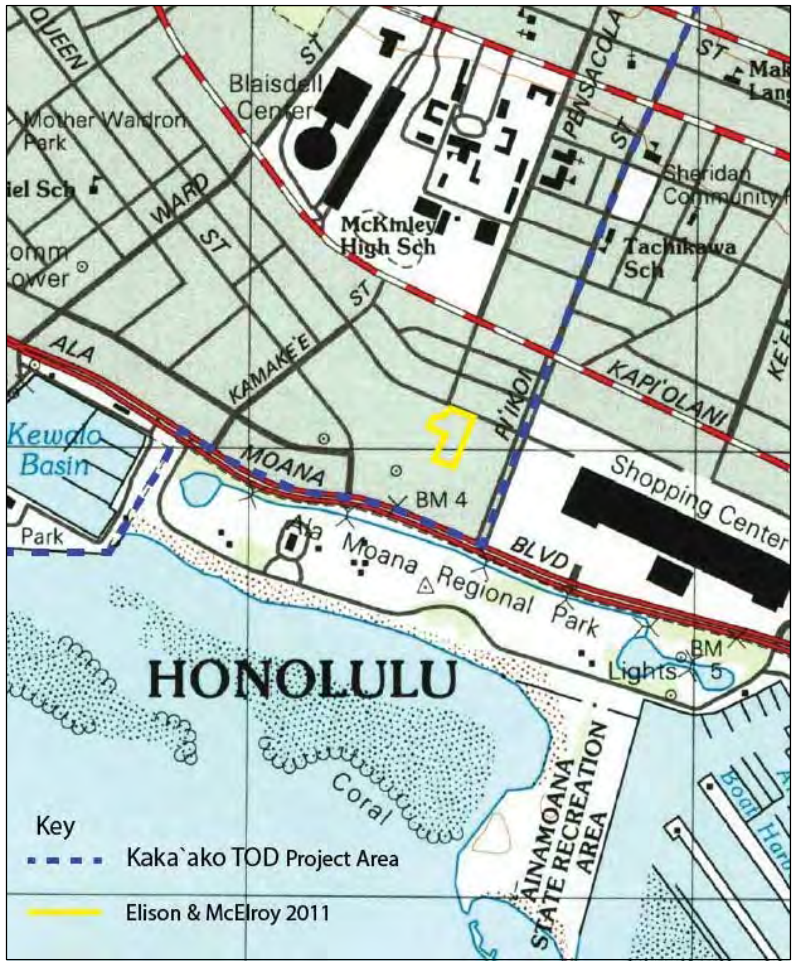

Figure 15. 1998 Honolulu Quadrangle U.S. Geological Survey 7.5-minute topographic map showing Elison and McElroy (2011) project area location.

4.2.1 Errors, Inconsistencies, & Ambiguities in Previous CIAs

The reviewed CIAs were checked for major errors, inconsistencies, and ambiguities. While most reviewed CIA were well researched and written, the scope of each report was limited to the project area's boundaries. According to the 1997 OEQC *Guidelines for Assessing Cultural Impacts*, "In scoping the cultural portion of an environmental assessment, the geographical extent of the inquiry should, in most instances, be greater than the area over which the proposed action will take place. This is to ensure that cultural practices which may not occur within the boundaries of the project area, but which may nonetheless be affected, are included in the assessment" (OEQC 1997:1). Areas adjacent to the project areas for each CIA study were not addressed in these studies. Each of the CIA studies were limited to the confines of the defined project area, which is not in accordance with the *Guidelines for Assessing Cultural Impacts* (OEQC 1997).

Wilson Okamoto and Associates, Inc. (2002) minimally performed research to summarize the ethnographic and historical background of its project area. While a two page summary was written for the archival research section, only one reference was cited (Clark 1977) and two Historic maps (Bishop 1884; Wall 1911) were presented. Overall, information provided in the background summary was accurate albeit a minimal effort and far from complete. Table 1 provides the key findings of Wilson Okamoto and Associates, Inc. (2002).

By and large, the background research results of Spearing et al. (2008) reflect thorough archival research methods as suggested by the 1997 OEQC *Guidelines for Assessing Cultural Impacts* and a diligent attempt to summarize the project area's cultural landscape from the pre-European Contact era into the Historic (Table 2). Yet, the *ahupua'a* designation –listed in this CIA as Waikīkī - should be clear and consistent with the report's text and maps. If the archival record is unclear, this should be further researched and an explanation as to why the project area was assigned to the *ahupua'a* of Waikīkī.

Overall, the results of background research in Vogeler et al. (2010) were very thorough and reflect a good faith effort to satisfy the 1997 OEQC *Guidelines for Assessing Cultural Impacts* as well as Act 50, SLH 2000 (Table 3). Some clarification of the *ahupua'a* designation is warranted.

The background research in Genz and Hammatt (2010) appears comprehensive and in accord with the OEQC *Guidelines for Assessing Cultural Impacts* (Table 4). Sections 3 and 4 of the report, which focus on the Traditional and Historical backgrounds, were exceptionally written, however, the Results of Background Research (Section 10.1 and Management Summary) contained a high frequency of repetition as well as disjointed and overlapping themes. The section could be better organized and simplified.

Elison and McElroy (2011) provided results of thorough background research. The background section, which presents numerous Traditional Hawaiian accounts as well as a large compilation of Historic documentation. The report was well-written and appears to exceed the *Guidelines for Assessing Cultural Impacts* (OEQC 1997) requirements. Table 5 provides the key background findings of Elison and McElroy (2011).

4.2.2 Results of Background Research

Generally, all of the CIAs for Kaka'ako exhibited thorough background sections, with the exception of Wilson Okamoto and Associates, Inc. (2002). Wilson Okamoto and Associates, Inc. (2002) simply summarizes the results of background research in the body of the CIA with a single reference cited (Clark 1977) and two Historic maps (Bishop 1884 and Wall 1911) provided as figures. The results of all Cultural Surveys Hawai'i, Inc., CIAs are listed in the Management Summary Sections of each report, as is the standard for Cultural Surveys Hawai'i reports. Elison and McElroy (2011) also summarize the background in the body of the report, providing the results of very thorough research. Tables 3-7 list the results of each report's background research.

Table 3. Wilson Okamoto and Associates, Inc. (2002) Results of Background Research

Wilson Okamoto and Associates, Inc. **(2010:iv-vii)**
1. Traditional name of general location that the University of Hawai'i Health and Wellness Center project area is situated on would have been the near shore waters off of Ka'ākaukukui, which is an *'ili* awarded to Victoria Kamāmalu in 1848 (LCA 7713). The land on which the project area sits was a Historic refuse landfill. Ka'ākaukukui was among several Bishop Estate properties acquired by the Territory of Hawai'i in 1919.
2. The project area is near to Kou, which is was a politically important harbor and village prior to European contact and is now the location of the city of Honolulu. King Kamehameha I moved the seat of government to Kou in 1809. The expansion of Kou affected the surrounding areas, including Ka'ākaukukui.
3. Historic Bishop (1884) map indicates that a "Beach Road" once ran along the shoreline and makai of the *'ili* of Ka'ākaukukui. This road appears to have become Ala Moana Blvd. The Wall (1911) map shows a retaining wall running along what is now Olomehani Street and the area makai of Ala Moana Blvd was filled with sediment by that time.
4. Unlawful residents came to inhabit the area and the area became known as 'Squattersville.' Wilson Okamoto and Associates, Inc. (2002) references Clark's (1977:64) description of 1920s Squattersville as a fishing village of roughly 700 people, mostly of Native and part-Hawaiians. The Territorial Government evicted the squatters in 1926.
5. Wilson Okamoto and Associates, Inc. (2002) also uses Clark's (1977) description of Ka'ākaukukui in the 1930s and 1940s, where the area is still a popular fishing and swimming area for the people of Kaka'ako. Clark (1977) maintains that there was a surf break called 'Stonewall' that local kids surfed on redwood planks. Marine resources were abundant and locals dove and caught a variety of fish and squid and also gathered limu and wana from the reef.
6. Wilson Okamoto and Associates, Inc. (2002) continue with Clark's (1977) description of how the City and County of Honolulu transformed Ka'ākaukukui into a dump in the late 1940s and early 1950s, extending a massive seawall seaward to retain the city's refuse. Kaka'ako Waterfront Park is situated on the footprint of the landfill.
7. According to Wilson Okamoto and Associates, Inc. (2002) the coastline continues to be utilized for a variety of recreational activities including fishing, swimming, and surfing as well as a gathering place for family picnics, barbeques, and parties.
8. The park and shoreline access areas are from the Kaka'ako Waterfront Park parking lot and several streets that terminate at the park.

Table 4. Spearing et al. (2008) Results of Background Research

Spearing et al.(2008:iii-v)
1. The current urban district known as Kaka'ako is significantly larger than the traditional area of the same name, which is described in mid 19th century documents and maps as a small *'ili* (traditional land unit). In addition to Kaka'ako, the Mauka Area District also includes lands once known as Ka'ākaukukui, Kukuluāe'o, and Kewalo, and possibly smaller portions of other *'ili*.
2. In traditional times, the study area is characterized by fishponds, salt ponds, trails connecting Honolulu (Kou) and Waikīkī, and occasional taro *lo'i*. Wetland/fishpond deposits have been documented in the Kaka'ako Mauka Area.
3. Previous archaeological work confirms that there are intermittent buried cultural layers in this near shore environment reflecting the Hawaiian pattern of permanent settlements in proximity to agriculture, aquaculture and marine resources.
4. There are four large historically documented cemeteries in the Mauka Area District. The full extent of these cemeteries has not been delimited and there are likely to be hundreds of burials associated with these cemeteries but outside the modern structures. Archaeological evidence has shown that during post contact times portions of the lands in and around the Mauka Area District were used to bury large numbers of people in unmarked cemeteries. A total of 274 historic burials have been recorded (*in situ* or disinterred) in the Kaka'ako Mauka Area.
5. Kaka'ako is a highly urbanized area with a mix of low, mid and high rise structures. There are no structures in the Mauka Area that predate or reflect the style of construction prior to western contact with native Hawaiians in 1778. A few remaining buildings were built by or inspired by nineteenth century missionaries, however, most buildings in Kaka'ako were built during the twentieth century after Hawai'i became a U.S. territory. To preserve Kaka'ako historic resources in accordance with Chapter 206E, HRS, the Draft Mauka Area Plan identifies eight properties to be protected. See Table 5. All eight properties are listed on either the National or State Register of Historic Places. The Draft Mauka Area Plan also proposes to protect the City and County of Honolulu's Neal Blaisdell Center for its cultural and aesthetic value.
6. The study area is associated with *mo'olelo* (oral history) in which Ka'ākaukukui, Kewalo and Kukuluāe'o were traditionally noted for their fishponds and salt pans, for the marsh lands where *pili* grass and other plants could be collected, for ceremonial sites such as Pu'ukea Heiau, Kewalo Spring, and Kawailumalumai Pond at which sacrifices were made, and for their trails that allowed transport between the more populated areas of Waikīkī and Honolulu. Important chiefs such as Hua-nui-ka-la-la'ila'i were born in the area and conducted religious rites, and commoners traveled to the area to procure food and other resources; some commoners probably also lived in the area, possibly adjacent to the ponds and the trails. The study area is also associated with legendary accounts of the Waters of Ha'o, Kapoi and the *heiau*, and the legend of Hi'iaka and more.

Table 5. Vogeler et al. (2010) Results of Background Research

Vogeler et al. (2010:iv-vii)
1. Covington's 1881 map indicates that the Project area is within Kewalo Ahupua'a and that the Kewalo Ahupua'a is comprised of Kaka'ako 'Ili on the east and Kukuluāe'o 'Ili on the west. While modern districting refers to Kewalo Ahupua'a as Kaka'ako District, the size and placement of the letters on Covington's 1881 map suggest that Kewalo is the larger land division, with Kaka'ako 'Ili and Kukuluāe'`o 'Ili inside this *ahupua'a*. Moreover, Kewalo is not a continuous *ahupua'a*. As the Hawaiian Government Surveys office explained in 1850: "Kewalo … had its seacoast adjoining Waikīkī, its continuous kula on the plain, and one-half of Punchbowl Hill and its kalo land in Pauoa valley" (see Section 4.2.1).

Vogeler et al. (2010:iv-vii)
2. From the *moʻolelo*, one can see that Kewalo, with the *ʻili* of Kakaʻako and Kukuluāeʻo, was noted for its fishponds and salt pans, for the marsh lands where *pili* grass and other plants could be collected, for ceremonial sites such as Puʻukea Heiau and Kewalo Spring, for Kawailumalumai Pond, where sacrifices were made, and for the trails that allowed transport between the more populated areas between Waikīkī and Honolulu.
3. Important chiefs were born in the Kewalo area and conducted religious rites, and commoners traveled to the area to procure food and other resources. Some commoners perhaps lived in the area, adjacent to the ponds and trails.
4. Perhaps the most famous *wahi pana* (storied place) of Kewalo is the fish pond called Kawailumalumai, or "Drowning Waters," used to drown *kauwā* or *kapu* (taboo) breakers as the first step in a sacrificial ritual known as *Kānāwai Kaihehe'e* (Kamakau 1991:6), or *Ke-kai-he'ehe'e*, which translates as "sea sliding along," suggesting that the victims were slid under the sea (Westervelt 1991:16). Early references indicate that Kawailumalumai Pond may have been near what was once the Ward Estate (now Neal Blaisdell Center).
5. Kewalo is located between two centers of population, Kou and Waikīkī, on the southern shore of pre-Contact Oʻahu. In Waikīkī, a system of taro *loʻi* (irrigated fields) fed by streams, descending from Makiki, Mānoa, and Pālolo valleys, blanketed the plain, and networks of fish ponds dotted the shoreline. Similarly, Kou (the area of downtown Honolulu surrounding the harbor) possessed shoreward fishponds and irrigated fields watered by ample streams descending from Nuʻuanu and Pauoa Valleys. The pre-Contact population and land use patterns of Kewalo may have derived from its relationship to these two densely populated areas; it may have participated in some of the activities associated with them.
6. By the 1840s LCA claims indicate that traditional Hawaiian usage of the region and its environs seems to have remained confined to salt making and farming of fishponds, with some wetland agriculture in those areas *mauka* or toward Waikīkī at the very limits of the field system descending from Makiki and Mānoa Valleys. Kewalo had a narrow upland section (often called "Kewalo Uka"), a larger lower river valley section, and a small coastal section (called "Kewalo Kai") joined by a small strip of land. The Project area is within this large LCA claim. Taro patches probably existed north of King Street. The lot south of the Project area consisted of fish ponds. It is evident from the 1855 La Passe map (Figure 9), that there were also once fish or salt ponds in the current Project area. An 1897 map (Figure 13) indicates that the swampy central Kewalo section was used to plant rice by the late nineteenth century.
7. The Ward Estate once covered a large portion of the Kakaʻako Mauka District. Curtis Perry Ward, a native of Kentucky, came to the Hawaiian Islands in 1853 and in 1865 married Victoria Robinson, who was descended from the Hawaiian *aliʻi* and early French and British residents. For his new family, Ward purchased at auction the 12-acre estate of Joseph Booth, Royal Patent 306, and additional contiguous lands in the Kōʻula area in 1870 (Hustace 2000:21–25). This constituted the *mauka* portion of "Old Plantation" from Thomas Square on King Street to the *makai* border at Waimanu Street. A few years later (before 1875), Ward added to his property with the purchase of 77 acres and 3,000 feet of ocean frontage in the *ʻili* of Kukuluāeʻo, *makai* of Queen Street. Workers were hired to clear the fishponds and ditches, plant taro in the fishponds, fence in pastures for the horse, plant 6,000 coconut trees, plant *kiawe* trees for firewood, and restore the *kāhaka* (salt pans) near the shore (Hustace 2000:41).
8. In 1930, her husband having died in 1882, Victoria Ward incorporated Victoria Ward, Limited to manage the estate. In 1957, the City and County of Honolulu purchased the *mauka* portion of the estate to construct the new Blaisdell Civic Center [sic] (Hustace 2000:67, 77).

Vogeler et al. (2010:iv-vii)
9. In 1907, when Honolulu High School moved from Fort Street to its new building on the corner of Beretania and Victoria Streets, two blocks north of its present location (Figure 18), the new school was named the President William McKinley High School. In 1898 President McKinley had signed the Newlands Resolution. From 1898 forward, Hawaiʻi was referred to as the Territory of Hawaiʻi (until 1959 when the official name changed to the State of Hawaiʻi). Due to an increase in students, a new site was acquired in 1921, just two block from its 1907 site. McKinley High School moved in 1923 to its present location between King Street and Kapiʻolani Boulevard, west of Pensacola Street (Figure 18). McKinley High School was the only public high school in Honolulu prior to the construction of Farrington High School in 1936. McKinley High School was particularly important for the first and second generation descendants of sugar plantation immigrant workers, and more than half of the student population was composed of students of Japanese descent in the 1930s (Odo 2004:76).
10. According to the McKinley High School website, "A statue of President McKinley was commissioned for $8,000. Completed in New York, the Bronze eight-ton statue was shipped to Honolulu and dedicated on February 23, 1911" (President William McKinley High School). In 1911, the *Pacific Commercial Advertiser* reported that the statue was intended to "immortalize his memory" (*Pacific Commercial Advertiser* 1911). The *Joint Resolution to Provide for the Annexing of the Hawaiian Islands to the United States* (1898), or Newlands Resolution, signed by President McKinley, is a U.S. domestic law, not an instrument of international law. No treaty of annexation was ratified under U.S. law. Yet the McKinley Statue holds a document labeled "Treaty of Annexation" (Figure 17).
11. After World War II, the Kakaʻako area became increasingly industrialized, and residents moved out to the newer subdivisions away from the Honolulu central area. A 1943 U.S. War Department map (Figure 16) shows the newly developed Kewalo Basin. A 1956 U.S. Army map of Oʻahu (Figure 20) illustrates the continued construction of buildings and fields at McKinley High School, including an athletic field within the current Project area.
12. In 2009, CSH completed an archaeological monitoring plan for a portion of the McKinley High School Athletic Complex Master Plan Project (O'Hare et al. 2009). This area included the softball stadium and the girl's locker room and shower facility. The monitoring plan specified that an archaeological monitor would be on-site during all ground-related disturbance activity below 18 in (0.45 m), due to the cultural sensitivity of the area and the number of burial finds already encountered in the vicinity of the project area. No fieldwork was performed under this monitoring plan.
13. In the accompanying AISP to this CIA, Burke and Hammatt (2010) determined the following: Burial densities in the vicinity of the present project area (which appears to have been mostly wetlands) could be expected to be lower than other areas where more sandy layers are present. Nevertheless, previous archaeological reports have documented human burials—both pre-contact Hawaiian and historic—throughout the greater Kakaʻako area, which includes the Kewalo area. Isolated burials and burial clusters have been found primarily in sandy deposits, just above the water table and below historic-era fill materials. Two documented historic cemeteries near the current project area were also located in sandy deposits.

Table 6. Genz & Hammatt (2010) Results of Background Research

Genz & Hammatt (2010:v-ix)
1. The location and extent of the area called Kakaʻako is ambiguous. The modern urban district of Kakaʻako is comprised of the *ʻili* (land section) of Kakaʻako and other lands once part of the extant *ahupuaʻa* (land division usually extending from the uplands to the sea) of Honolulu.

Genz & Hammatt (2010:v-ix)
2.The Kakaʻako area has been heavily modified over the last 150 years due to historic filling of the area for land reclamation; however, the fill has served as an agency of preservation rather than destruction of the patterns of early Hawaiian life and the remains of nineteenth century Honolulu and Waikīkī (Griffin et al. 1987:73). Much of the *wahi pana* (storied places), *loko iʻa* (fishponds), *heiau* (shrines), and other cultural resources, and natural deposits and land forms of the area have survived below this fill. Accompanying *moʻolelo* (stories, oral traditions), *oli* (chants), *ʻōlelo noʻeau* (proverbs), and *wānana* (prophecies) have been documented that still resonate with Hawaiians of the Kakaʻako district today.
3. The *ʻili* of Kakaʻako and surrounding lands remained outside the two most intensely populated and cultivated areas on southeastern Oʻahu—Waikīkī and Honolulu—during pre-Contact times, yet Hawaiians used the lowland marshes, wetlands, salt pans, and coral reef flats for salt making and farming of fishponds along with some limited wetland taro agriculture (Kotzebue 1817), and this supported habitation sites clustered around the *mauka* (inland) boundary of the Kakaʻako area near Queen and King Streets (LaPasse 1855).
4. The salt marshes were excellent places to gather pili grass for the thatching of houses, which may have led to the name Kakaʻako (prepare the thatching) (Thrum 1922:639). *Moʻolelo* point to the coastal marshes of Kewalo as the habitat of the original *pueo* (owl) that became one of the Hawaiians' *ʻaumākua* (deified ancestors) (Westervelt 1963:135–137; Thrum 1998:200–202). The *moʻolelo* of Kawaiahaʻo follows a trail between Waikīkī and Honolulu to locate two freshwater springs—Kewalo Spring and Kawaiahaʻo (The Waters of Haʻo) (Pukui 1988:87–89), which highlights its location between the two main population centers.
5. Kewalo was once associated with a spring called Kawailumalumai (drowning waters, Sterling and Summers 1978:292) that was used to sacrifice *kauwā*, or members of a pariah caste, designed for the *heiau* of Kānelāʻau on the slopes of Pūowaina (Punchbowl) as the first step in a drowning ritual known as Kāneāwai Kaihehe'e (Kamakau 1991:6) or Ke-kaihe'ehe'e (sea sliding along) (Westervelt 1963:16).
6. Puʻukea Heiau (white hill), which belonged to the chief Huanuikalalaʻilaʻi, was possibly located on one of the few elevated locations in the flat, low-lying swamp that surrounded it. *Kāhuna* (priests) used *mahiki* (a kind of grass) of Puʻukea, which grew on the nearby coast, to exorcise malicious spirits from the afflicted (Pukui and Elbert 1986:219), a concept that still resonates with the contemporary usage of *mahiki* in lines of *hoʻoponopono* (family conference in which relationships are set right) inquiry to "peel off" layers of deeper feelings (Pukui et al. 1972:228).
7. Land Commission Award (LCA) documents reveal that much of the land in Kakaʻako was used to produce salt, including: salt ponds near the shore that filled with salt water at high tide (*ālia*), drains where the salt water from these pans was transferred to smaller clay-lined or leaf-lined channels (*hoʻoliu*), natural depressions in the rocks along the shore where salt formed naturally (*poho kai*), and land (*kula*) that could probably not be used for agriculture as it was impregnated with salt (LCA 1903). The abundance of salt led to the Kakaʻako Salt Works in the late nineteenth century (Hustace 2000:50).
8. The Kakaʻako area continued to remain outside Waikīkī and Honolulu during the post-Contact era. It served as a place of the dying and the dead, of isolation and quarantine, of trash and wastelands, and the poor and the immigrant; however, it also represents the birth of modern Waikīkī and Honolulu (Griffin et al. 1987:73). Specifically in this area: victims of the 1853 smallpox epidemic were quarantined in a camp (Thrum 1897:98) and those that did not survive were buried at Honuakaha Cemetery (Griffin et al. 1987:13); Hansen's Disease patients were treated in the Kakaʻako Leper Branch Hospital (Griffin et al. 1987:55); victims of the 1895 cholera epidemic were treated at the Kakaʻako Hospital (Thrum 1897:101); infected patients of the 1899 bubonic plague were moved to a quarantine camp; animals were quarantined in a station in 1905; and the city's garbage was burned in an incinerator at Kewalo Basin (UH 1978).
9. After the annexation of the Hawaiian Islands by the United States in 1898, the U.S. Congress began to plan for the coastal defenses of their new islands, which included Fort Armstrong on the Kaʻākaukukui Reef as a station for the storage of underwater mines. In 1911, the Honolulu Rifle Association, and possibly other groups, used the flat, uninhabited Kakaʻako lands near the coast as a rifle range (Williford and McGovern 2003:15).

Genz & Hammatt (2010:v-ix)
10. The late nineteenth and early twentieth centuries were a time of intense development of the coasts of Honolulu, Kakaʻako, and Waikīkī. A number of land reclamation projects dredged offshore areas to deepen and create boat harbors, and used the dredged material to fill in the former swampy land. Kakaʻako became a prime spot for large industrial complexes, such as iron works, lumber yards, and draying companies (Nakamura 1979).
11. Kewalo Basin harbor was formerly a shallow reef that enclosed a deep section of water that had been used as a canoe landing since pre-Contact times and probably was used since the early historic period as an anchorage. Dredging of the Kewalo Channel began in 1924, but by the time the concrete wharf was completed in 1926, the lumber import business had faded, so the harbor was used mainly by commercial fishermen. In 1941, the government dredged and expanded the basin to its current 22 acres. In 1955, workers placed the dredged material along the *makai* (seaward) side to form an eight-acre land section protected by a revetment—now the Kewalo Basin Park (Kewalo Basin Harbor 2009).
12. In 1899, Gorokichi Nakasugi, a Japanese shipwright, brought a traditional Japanese sailing vessel, called a *sampan*, to Hawaiʻi, and this led to a unique class of vessels and distinctive maritime culture associated with the rise of the commercial fishing industry in Hawaiʻi (Van Tilburg 2007). Japanese-trained shipwrights adapted the original *sampan* design to the rough waters of the Hawaiian Islands (Krauss 2006). The fishermen used a traditional live bait, pole-and-line method of fishing and unloaded their catches of *aku* (bonito, skipjack) and *ahi* (yellow-fin tuna) at Kewalo Basin (Van Tilburg 2007:43). The *sampan aku* fleet relocated to Kewalo Basin by 1930, and the McFarlane Tuna Company (now Hawaiian Tuna Packers) built a shipyard there in 1929 and a new tuna cannery at the basin in 1933 (Clark 1977:64). The *sampan* fishing industry declined dramatically following World War II, such that today the *Kula Kai*, built in 1947, is the only surviving vintage wooden *sampan* in Hawaiʻi (Krauss 2006).
13. Previous oral histories of Kakaʻako residents documented the lives of the "unsung heroes" of Kakaʻako from the early twentieth century—the machinists, firemen, cannery workers, and others from diverse ethnic backgrounds that shaped the history of Hawaiʻi (UH 1978). Many of the interviewees were of Japanese descent, and many of their fathers were fishermen who settled in Kakaʻako to have access to the waterfront. Usaburo Katamoto, a boat builder, described 35-foot *aku sampan* "sailing in the fair wind" off the Kewalo Basin harbor and Pearl Harbor, and that he used to dray the newly built vessels with a team of a dozen mules (UH 1978:534-632). Keisuke Masuda, a foreman at Hawaiian Tuna Packers, described in detail how at night he and a small crew of transient Filipinos unloaded the fish from the *sampan*, weighed the fish, operated the boiler, and steamed the fish, and how 200 Japanese women cleaned the fish and packaged the canned tuna (UH 1978:817-876).
14. As a result of the dredging, no pre-twentieth century burials or other pre-twentieth century finds would be expected in the immediate vicinity of the harbor, and there is no documented evidence from archaeological surveys, historical records, or oral traditions of *ilina* (graves) or *iwi kūpuna* (ancestral remains) within the Project area. However, the adjacent lands of Kakaʻako contain two large cemeteries and numerous burials, and human skeletal remains were discovered near the former coastline on the *mauka* side of Kewalo Basin at the intersection of Ala Moana Boulevard and Kamakeʻe Street (Souza et al. 2002). Further, the original foot path at the edge of the former coastline has been transformed through time to a horse path, buggy and cart path, and finally to the widened Ala Moana Boulevard. As a result, early twentieth century human burials and other cultural resources could potentially be located adjacent to the *makai* curb of Ala Moana Boulevard, but any lands seaward of the old trail were probably too close to the water table and too unstable to have been used for permanent habitation or burials (Hammatt and Shideler 2010).
15. During the first half of the twentieth century, the marshlands and rice fields in the Kakaʻako district were filled to accommodate the expanding urbanization of Honolulu. Poverty-stricken settlements arose in the 1920s, camps of Hawaiians, Portuguese, Chinese, and Japanese settlers developed in the 1930s, and the area became increasingly industrial in the 1940s. In the 1960s, the explosive growth of surfing in Waikīkī forced many surfers to explore and discover uncrowded breaks, including the waters of Ala Moana Beach Park and Kewalo Basin (Clark 1977:64)

Table 7. Elison & McElroy (2011) Results of Background Research

Elison & McElroy (2011:58-59; 103)
1. [Kaka‘ako was] Once a low, swampy area which has consequently undergone development through the addition of fill, Kaka‘ako was situated between the two royal centers located in Honolulu (formerly Kou) and Waikīkī. Place names and *‘ōlelo no‘eau* associated with Kaka‘ako highlight the natural resources, with the area of Kukuluāe‘o being named after the *ae‘o*, or the Hawaiian Stilt which found refuge in the area’s salt ponds. *‘Ōlelo no‘eau* associated with Honolulu, Kou, Kewalo, Kālia and the seas of Kuloloia and Māmala reveal a place that many, including *ali‘i*, frequented for various purposes such as the playing of *kōnane*, playing music, fishing and gathering resources such as *alamihi* crabs and salt (Elison and McElroy 2011:58).
2. *Mo‘olelo* referring to Kaka‘ako, Kewalo and Honolulu also offer insight into the natural landscape and traditional practices of the area. In these *mo‘olelo*, Kaka‘ako is the stage upon which legendary figures such as ‘Ai‘ai, son of the fishing god Ku‘ula, meets his wife and creates fishing *ko‘a* (shrines) (Elison and McElroy 2011:58).
3. Historic accounts and artistic renditions of Honolulu, Kewalo, Kālia and Kaka‘ako provide valuable information on traditional land use practices and topographic elements dating to the pre- and early post-Contact eras. The landscape of Kaka‘ako is generally depicted as flat, warm and cultivated, with trails meandering through *lo‘i kalo* and inland fishponds. Many artistic renditions show habitation sites, as well as the marshy salt ponds which typify this area of O‘ahu's southern shore (Elison and McElroy 2011:58).
4. Mele of Kaka‘ako and its vicinity reveal information coinciding with *‘ōlelo no‘eau* and historic accounts regarding land use and also presents the opportunity to better understand the lives of its inhabitants in the nineteenth and twentieth centuries. As with any area, *mele* address a diverse array of subjects and express infinitely many sentiments. Those associated with Kaka‘ako are no different and include chants referring to the birth of chiefs such as Hua-a Kamapau, which was born in Kewalo, *mele* about being quarantined for cholera and mele referring to the alcoholic drinks served at the old Kewalo Inn. This diversity of *mele* exemplifies the many changes which make the area of Kaka‘ako such a historically significant place (Elison and McElroy 2011:58-59).
5. Land Commission Awards are a highly valuable resource for identifying traditional land use practices. Examination of testimony describing the lands of the subject property and the surrounding area reveals the high frequency of taro ponds, *ki‘opua* (ponds for young fish), pasture land, and few house sites. Previous archaeological investigations also present supporting data, recording many subsurface cultural sits associated with various pond sediments. Archaeological records also produce valuable information regarding pre-Contact use of Kaka‘ako, as well as the high frequency of human burials within the area, many of which are likely to be associated with the number of diseases that ravaged Hawai‘i’s population (Elison and McElroy 2011:59).
6. Previous ethnographic studies of Kaka‘ako contain valuable information about life in Kaka‘ako during the 1900s. Oral history interviews conducted with previous residents shed much light onto this once heavily populated area and its significant and dynamic history (Elison and McElroy 2011:59).
7. The background study revealed that Kaka‘ako was a culturally significant area with many natural resources which supported traditional subsistence activities such as fishing, the gathering of plants, *limu* (seaweed), the production of *pa‘akai* (salt), and supporting numerous inland fishponds used to raise mullet and *awa*, as well as *kalo* (Elison and McElroy 2011:103).
8. The location of Kaka‘ako, between active royal centers in Honolulu and Waikīkī, has shown that it was an integral location ideal to support food and salt production activities which fed the *ali‘i* and the royal families (Elison and McElroy 2011:103).
9. Kaka‘ako’s history also provides insight into the plights of thousands of people, of all ethnicities who fell as victims to the various diseases which struck Hawai‘i in the 1800s. One could surmise that, due to the population density of Kaka‘ako within the environs of Honolulu, the region was one of the hardest hit locations in all of Hawai‘i (Elison and McElroy 2011:103).

4.2.3 Results of Community Consultations

The CIA performed by Wilson Okamoto and Associates, Inc. (2002) did not follow the protocol listed in the *Guidelines for Assessing Cultural Impacts* (OEQC 2011) in terms of identifying and consulting with individuals and organizations having expertise in cultural resources, practices, and beliefs on the subject area. No individuals were identified as cultural informants nor were any ethnographic interviews or community consultations performed.

Spearing et al. (2008), dispatched requests for participation to eighty-one community members representing government agencies, community organizations, and individuals, including such stakeholders as Kaka‘ako residents, cultural and lineal descendants, as well as cultural practitioners. A total of thirty-four cultural informants, comprised of twelve *kūpuna* (elders) and/or *kama‘āina* (native-born) responded to these requests and participated in interviews. These consultations founded 5 major concerns over adverse impacts on cultural, historic, and natural resources as well as cultural practices and beliefs potentially initiated by the proposed Kaka‘ako Mauka Area Plan. Table 6 provides the Management Summary of Community Consultation Results presented by Spearing et al. (2008: v-vii). However, the Spearing et al. (2008) Results of Community Consultations (Section 10.2 and Management Summary) minimally recapitulates the Community Consultations (Section 6), Summaries of Kama‘āina Interviews (Section 7), and Consultation of Cultural and Lineal Descendants (Section 8). Much more detail from the interviews is warranted with distinct cultural resources and practices organized or listed. Additionally, areas adjacent to the Kaka‘ako Community Development District Mauka Area Plan project area were not assessed, which is a directive of the *Guidelines for Assessing Cultural Impacts* (OEQC 1997:1).

The results of Vogeler et al. (2010) were based upon five formal interviews, though twenty individuals were contacted. Some of the report was supplemented with project area information presented in previous Cultural Surveys Hawai‘i, Inc., CIA reports. Table 7 lists the Management Summary of Community Consultation Results presented by Vogeler et al. (2010: vii-x). The results of Community Consultations in Vogeler et al. (2010) reveal some sentiments regarding the changing cultural landscape of McKinley High School. One concern is that the “Hawaiian” feeling on campus, in terms of architecture and use of traditional plants as well as ethnic diversity, which once gave some of the informants a sense of place and comfort, has dwindled since the informants had left the school. Another concern is that the McKinley statue and plaque mislead those not familiar with the history behind the figure and his policies. While the project area itself was adequately assessed, the scope of the assessment was limited to the McKinley High School Athletic Complex project boundaries, which is not in keeping with the *Guidelines for Assessing Cultural Impacts* (OEQC 1997:1), which states that adjacent areas be assessed as well.

Genz and Hammatt (2010) made efforts to contact thirty-nine cultural informants, each representing either themselves as cultural or lineal descendants, residents, community members, and/or cultural practitioners as well as government agencies and community organizations. Six individuals, made up of *kūpuna* and *kama‘āina* were interviewed. Table 8 provides the Management Summary of Community Consultation Results presented by Genz and Hammatt (2010: ix-xi). Through comprehensive community consultations, Genz and

Hammatt (2010) have provided new insights on the cultural significance of the Kewalo Basin and surrounding land and water. Several cultural groups and resources were identified that may be impacted by the proposed harbor improvements, including the *Kula Kai*, which the last operating *aku sampan* in Hawai'i, as well as surfers, practitioners of *lā'au lapa'au,* and fishermen among others. Overall, Genz and Hammatt (2010) have demonstrated due diligence under the 1997 OEQC *Guidelines for Assessing Cultural Impacts* as well as Act 50, SLH 2000. Yet, the scope of the assessment should cover areas adjacent to the project boundary and the summary of cultural resources and practices identified could be much more concise.

While eighty-eight request letters were sent to cultural descendants of Kaka'ako area and requests sent to nine Native Hawaiian organizations, a total of eight ethnographic interviews were included in Elison and McElroy (2011). Interviewees had varied connections to Kaka'ako, including individuals who were born and/or raised in Kaka'ako, as well as those who traced their lineage to Kaka'ako. Several themes, referred to as "Topical Breakouts," were investigated during these interviews: Personal Connections to Kaka'ako, The Past: Pre-Contact Kaka'ako, The Past: Post-Contact Kaka'ako, and Today: Kaka'ako and Ko'olani Phase II Plans. Interviewees shared first-hand knowledge and the *mana'o* that was passed down to them from their **kūpuna** to address these themes. Table 9 summarizes Elison and McElroy's (2011) ethnographic interview findings.

Table 8. Spearing et al. (2008) Results of Community Consultations

Spearing et al. (2008:v-vii)
1. The Mauka Area District and vicinity is likely to have surface and subsurface cultural and historic properties, including human burials. Several of the study participants indicated that there could be *iwi kūpuna* (ancestral remains) in or near the subject Mauka Area District. Phyllis "Coochie" Cayan of SHPD states, "As you know from past and current projects in the area and the ahupua'a—the makai area is a high risk for human burials. There has been past inadvertent finds mauka, but not as numerous as the makai areas." Study participants made the following recommendations: a. Due to the fact that the Mauka Area District is likely to have surface and subsurface cultural and historic properties, Hui Mālama I Na Kūpuna O Hawai'i Nei has recommended a thorough, in-depth archaeology inventory survey. OHA recommended for every developer within HCDA's jurisdiction to conduct an archaeological inventory survey to identify *iwi kūpuna* as the probability of burials and other cultural properties in the Mauka Area District is high. b. Cultural descendant Paulette Kaleikini has stated that, "any/all burials must be preserved in place and left undisturbed." She also requested that "a cultural monitor be on duty each and everyday during the survey and testing and also that a detailed record of any/all *moepū (*funerary objects) and artifacts be kept." c. OHA, SHPD, Hui Mālama I Na Kūpuna O Hawai'i Nei, Leimomi Khan, Charles Kapua, Dr. Claire Hughes, Paulette Kaleikini and Paulette Moore state that *iwi kūpuna* finds be protected and treated respectfully.

Spearing et al. (2008:v-vii)
2. Several participants voiced negative feelings and concerns about the overall cumulative impacts of ongoing and future developments in Kaka'ako and Mauka Area District environs as contributing to the loss of what is authentic and traditional about Kaka'`ako. Study participants mentioned factors such as: housing prices and rental space for businesses being beyond the reach of most *kama'āina* and the displacement of local, family businesses by national chains. A few participants provided suggestions for development projects that might generate more tourism to the area while maintaining a Hawaiian sense of place and the look and feel of "old Kaka'ako" including: (a) creating a pedestrian overpass over Ala Moana Boulevard to Kewalo Basin, (b) refurbishing the fish auction house, (c) creating a monument in Kaka'ako as a repository for genealogies of the Hawaiian monarchy, (d) creating a Hawaiian "cultural market" and, (e) providing local businesses with lower rent.
3. A related concern is the loss of historic properties in the Mauka Area District and vicinity. The Historic Hawai'i Foundation (HHF) referred CSH to an inventory study prepared by Fung Associates for General Growth Properties (GGP) (2008) in which 13 parcels were identified within the master plan boundary that contain structures of historic integrity that will become eligible for designation on the State Register of Historic Places within the 30 year planning horizon. HHF emphasized that of the 13 parcels identified in the 2008 Fung Associates inventory for state and national registers of historic places, the IBM Building at 1240 Ala Moana Boulevard designed by Vladimir Ossipoff (1962) is significant for its distinctive architecture and the work of a master and is thus eligible for designation on the Hawai'i Register of Historic Places. HHF further recommended for this CIA that, …similar study and evaluation of the remaining blocks to be conduced and that the findings from the GGP inventory be incorporated. Notable sites will include those already listed on the Hawai'i State or Nation Registers of Historic Places, such as McKinley High School and the Ala Moana Pumping Station, as well as…the Dickey-designed theater, WWII-era and post-war Quonset huts, modernist structures at the Blaisdell complex, and other residential, commercial and industrial buildings throughout Kaka'ako. Community contacts interviewed for this study also noted the significance of historic properties in the Mauka Area District and vicinity and stated their desire to see the preservation and/or rehabilitation of properties in or near the Mauka Area District such as Fisherman's Wharf, Ward Farmers Market (formerly, Ala Moana Fish Market), Mother Waldron Neighborhood Park, Kewalo Theater and buildings on Queen Street such as the Quonset huts and the Hamada H. Store.
4. Some participants voiced opposition to the development, construction or alteration of Kaka'ako that threatens to negatively impact its view corridors and remaining green spaces (parks). Participants are concerned that high rises will further obstruct *mauka-makai* views; one participant stated his concern that further high rises would create a wind tunnel; another participant recommended that building height be limited to 40 feet. Two participants provided suggestions to help remediate the loss of green spaces and to protect the natural environment including: pursuing a green initiative by, for example, using a deporter that transfers deep, cold ocean water to power air conditioners in buildings close to the shoreline; creating a Hawaiian garden with plants that people used and use in everyday life such as *kukui* (*Aleurites moluccana*) and *tī* (*Cordyline fruticosa*).
5. A few participants expressed concern about the study area's overtaxed infrastructure mentioning, for example, streets in disrepair, traffic congestion and waste management problems as a result of current and future developments in Kaka'ako.

Table 9. Vogeler et al. (2010) Results of Community Consultations

Vogeler et al. (2010:vii-x)
1. The two McKinley High School alumni celebrated the diversity of the school. State Senator Suzanne Chun Oakland thus describes the culture of McKinley High School: McKinley has always had a very diverse population of people, so we celebrated culturally. We had a May Day program during the day and in the evening. And we had all the students share their cultural practices, whether it was games, food, different kinds of dances, song. So, I don't know if there has been that kind of continuation. But I know that when I was there, I really wanted to celebrate the diversity of our cultures there. You had over 3,000 teachers because every student was a teacher for me, personally. When thinking back to the late-1950s and early-1960s, Ms. Pi'ilani Kaopuiki similarly describes a community where there was an exchange of cultural foods and ideals. For Ms. Kaopuiki, the community has changed: "the warmth and welcome has gone: evaporated." Yet, Ms. Kaopuiki also notes that McKinley High School's lack of Hawaiian cultural significance as the primary trait of the school: "To me, the cultural significance of McKinley (High School) is that it doesn't have any Hawaiian culture in its physical plans now. It looks like wherever it came from…someplace in Europe."
2. Plants and agriculture of Kewalo were once an important part of the school curriculum and the culture. Senator Chun Oakland recalls a club at McKinley High School for Future Farmers of America and many other clubs, as well as a robust agricultural program before she became a student. While she was a student, these clubs and the agricultural programs "just did planting on the school site. My understanding before is that they used to go to the farms and be able to take care of the farms. That was part of the curriculum." Mr. Charles Kapua remembers various plants that were gathered from the *ahupua'a* (land division usually extending from the uplands to the sea) near the Project area, including banana stumps, *kōko'olau* plants, *kamani* leaves, and *wiliwili* berries. One unnamed participant gathered medicinal plants for *lā'au lapa'au*. These included *'uhaloa, pōpolo*, *māmaki*, *kī* and *laukahi*. The *'uhaloa* and *laukahi* were gathered on the McKinley High School campus. This anonymous participant identifies plants as part of Hawaiian sensibilities. She believes that, "the grounds could use some work…. I hope they keep the Hawaiian flavor too—and not be so sterile…. I think the plantings and grounds should blend with the style of these stately buildings." Ms. Kaopuiki similarly believes that native plants should be included in the new landscaping: "My hope is that they will incorporate native plantings. You're going to have plantings— then use native plantings because we have them available now."
3. As far as fishing in the area, Ms. Kaopuiki heard of net fishing and pole fishing near Ala Moana and the Kewalo Basin, fishing from the shoreline and in boats. For Uncle Charles Kapua, his grandfather on his mother's side had a sampan boat that would go out to catch fish in Kewalo Basin. They would catch *aku, 'ōpelu, akule* and other fish. When asked if he remembered the names of the *aku* boats, he remembered the Yellowfin aku boat. The unnamed participant fished in the harbor and caught several kinds of reef fish, including 'aweoweo, *manini, opelu, 'aholehole*, and *'ama'ama*, and squid (see Appendix B).

Vogeler et al. (2010:vii-x)
4. All participants spoke of a sense of place, in one way or another. However, this idea meant different things to each individual. For Ms. Kaopuiki: A sense of place means that you recognize that we have trade winds, and try to use that in the design. That's the sense of place. I've been to some places that as soon as you get off the airplane, and you see the buildings, you know that you are in someplace different because their designs speak of where they are: Sāmoa. It's hard if you are in a city. But these people have an opportunity, especially since they're not going to build towers, where towers have to meet certain conditions, they can design so that there's a sense of being in Hawai'i. Senator Chun Oakland associates this sense of place with the architecture of the schools and the surrounding area: "What has been associated with McKinley [High School] are the beautiful grounds that we have. The historic buildings that we were able to preserve. So, I really hope that kind of ambiance is kept." Uncle Charles recommends building structures that match the existing architecture of the school.
5. While the McKinley Statute does not fall within the Project area, three of the five participants interviewed mentioned the inaccuracy of the McKinley Statue specifically. While the statue is a source of pride for one participant in this study, the three Native Hawaiians interviewed spoke of the inaccuracy of the depiction. Some viewed the "Treaty of Annexation," held in the statue's hand, as an attempt to misrepresent history. Ms. Kaopuiki explains that: This school is named in honor of someone whose place in Hawaii's history is not one of pride. Wouldn't it be nice if it was decided that, because the school is an educational institution and should represent truth, that President McKinley doesn't deserve such honorable recognition—here in Hawai'i anyway. The name of the school should be changed and the statue removed. Mr. Kapanui also recalls that, "There was some controversy about the statue in front of the auditorium. That the document had something to do with—something that really wasn't what it was all about—something to do with the overthrow."
Mr. Kapua, a U.S. veteran and a McKinley High School alumnus, recommends that the truth regarding the McKinley Statue be addressed: "If not now, then when?" The statue holds a document, and the words on the document are "Treaty of Annexation": Mr. Kapua believes that a plaque should be erected in front of the statue to draw attention to the inaccuracy, thus remedying the wrong. He does not believe this is a matter of rewriting history, but instead honestly portraying the truth of history. He also believes that a plaque is more respectful and less costly than taking down the statue and fixing it.

Table 10. Genz & Hammatt (2010) Results of Community Consultations

Genz & Hammatt (2010:ix-xi)
1. *Wahi pana* and *mo'olelo* associated with the Project vicinity reveal a strong connection to past traditions and a renewed salience of those traditions today. Mr. Kapanui explains that Hawaiians traditionally dedicated newly constructed *heiau* to the war god Kū and other primary male gods and christened special events with human sacrifices. He shares a *mo'olelo* of sacrificial drowning at the waters of Kewalo Basin and an inland pond located at the Blaisdell Center, a story that Mr. Kapanui uses today to enrapture visitors. According to Mr. Kapanui, *ali'i* (chiefs) associated with two sacrificial *heiau*— Kānelā'au Heiau on the slopes of Punchbowl Crater and a *heiau* near the former coastline at the Kawaiaha'o Church—required that members of the low *kauwā* caste were strangled underwater to ensure the victim's body remained intact without excessive blood and bruises.

Genz & Hammatt (2010:ix-xi)
2. The identity of the descendents of former Kaka‘ako residents is influenced by *mo‘olelo* of the area as a place of coral flats, landfill, dumps, disease, and death. Mr. Kapanui describes how the smallpox epidemic of 1853 ravaged Hawai‘i. According to Mr. Kapanui, over 3,000 small pox victims were buried in mass graves near the former coastline at Restaurant Row and the old Kaka‘ako Fire Station. Older firemen have shared with Mr. Kapanui their experiences of ghost haunting there.
3. *Kama‘āina* of Kaka‘ako fondly reminisce about the diverse ethnic neighborhoods of Kaka‘ako and the recreational use of the waterfront during the 1930s and 1940s. A confidential participant portrays the vibrant and interactive character of the Japanese, Chinese, Filipino, and Portuguese immigrant families. Mrs. Kekina remembers swimming in the harbor and cove of Kewalo Basin and nearby reefs.
4. Despite intense dredging and land reclamation in Kaka‘ako, knowledge of *lā‘au lapa‘au* (traditional plant medicine) and customs of gathering plants for medicinal and agricultural purposes continue to be passed on by Hawaiians of Kaka‘ako. A confidential participant explains in detail the collection, preparation, and medicinal uses of the following plants: *‘uhaloa*, castor beans, guava, *pōpolo*, *tī*, and *māmaki*, as well as the gathering and consumption of several types of *limu* (seaweed), including *limu ‘ele‘ele*, *limu ogo*, and a type of *limu* that grows on *‘opihi* (limpets) (see Appendix B for common and scientific plant and animal names mentioned by community participants).
5. The historic era of *aku* fishing and *sampan* of Kewalo Basin still resonates with community members today. Mrs. Kekina gives a voice to the few remaining descendents of the original Japanese immigrant fishermen of the early twentieth century. Her father worked as the shipyard foreman for Hawaiian Tuna Packers and built *sampan* boats for *aku* fishing. Mr. Moses describes the small, vibrant community of *aku sampan* fishermen in the late 1960s. The crew regularly gathered on the shore of the harbor on the present-day eastern parking lot and later in a small building near the harbor entrance (now used by the charter school Hālau Kū Māna) to repair their nets, which reached lengths of 200-300 yards. Several fishermen continue to practice the swiftly declining unique maritime tradition of *aku sampan* fishing. Mr. Nihoa and Mr. Moses describe the unique specificity of the Japanese-designed *sampan aku* boats and detail the techniques of *aku* fishing.
6. The waters of Kewalo Basin once contained numerous reef fish. Mrs. Kekina fished at the Kewalo Cove for menpachi, which her mother then cooked for an exceptional recipe of miso soup and a confidential participant caught several reef fish at Kewalo Basin, including *‘āweoweo*, *manini*, *‘ōpelu*, *āholehole*, *‘ama‘ama*, and squid (octopus).
7. According to Mr. Iwami, the charter school Hālau Kū Māna leases the old net house at the Kewalo Basin Park and maintains a garden near the harbor channel of at least 13 native Hawaiian plant species. (See Section 9.2 for Hawaiian and scientific names of these plants as they appear on labeled signs).
8. Traditional Hawaiian culinary practices live on for *kama‘āina* of Kaka‘ako. A confidential participant explains the preparation of pigs and fish for *lū‘au* (feasts). In addition, Mr. Nihoa and Mr. Moses continue the practice of drying *aku* at sea for home consumption. The boat they work on is evidence of the continued consumption of fresh *aku* as well.
9. A tight-knit intense social community of surfers has emerged at “Kewalos,” a series of four surf breaks adjacent to the harbor entrance in front of the Kewalo Basin Park. Mr. Iwami describes the meanings of the surf breaks (Marine Land, Straight Outs, Rennicks/Right Next, and the Point), as well as the neighboring body surfing break located west of the harbor channel in front of the Kaka‘ako Waterfront Park (Point Panic). Mr. Iwami suggests that the excellent surfing conditions, the short section of oceanfront land, and the single entrance to the park have contributed to the enduring social bonds of the Kewalos surfers.
10. The respondents are not aware of any cultural or historic properties, including *ilina* or *iwi kūpuna*, within or adjacent to the current Project area. However, Mr. Moses and Mr. Nihoa highlight the cultural significance of the *Kula Kai*, the last of the original wooden *sampan aku* boats in Hawai‘i which was built just after World War II and is docked at Kewalo Basin.

Table 11. Elison & McElroy (2011) Results of Community Consultations

Elison & McElroy (2011:70-102)
1. Traditional Sites: Kawaiaha‘o was verified as a pre-Contact Hawaiian site; *heiau* of Pākākā was located in Kuloloia
2. *Mo‘olelo*: several *mo‘olelo* (mostly of the spooky variety) were relayed about Kaka‘ako: the graveyard area by Kawaiaha‘o Church was associated with apparitions of a white horse and horseless man; in a vacant lot near the residential area, supernatural fireballs were observed by several inhabitants
3. Traditional name for the Elison and McElroy (2011) project area: Kuloloia Waterfront, Stream, Harbor, and Reef (referencing several books, quotes, and annuals written on the subject); also Kuloloia as the location that was sovereign, according to Bernice Pauahi Bishop; and referenced in a speech by Lunalilo: “…from the Waters of Keomo struck the first blow on Big Island to the *hui lokahi ana o na Mokupuni i ke kai o Ku-loloia* – everybody coming together building the government at the *kai* of Kuloloia…” (Elison and McElroy 2011:73); Historic era news article talked about the *awa* (bay) of Kuloloia and a ship named Mohongo going into the bay; Kuloloia also had famous markets, named Pakele or Hui Pakele and Hui Kalepa Ho‘okuonoono Hawai‘i
4. *Oli*: Kaka‘ako, Kālia, Māmala, and Kuloloia mentioned in numerous chants that can be found in the Bishop Museum
5. Burials: Kaka‘ako in general and specifically the Elison and McElroy (2011) project area said to have *iwi kūpuna*; many Native Hawaiians in Kaka‘ako were destitute and subsequently fell victim to epidemics in mid-1800s and buried near to where they lived; on Ke‘eaumoku Street there is make-shift cemetery for 250 people that died during epidemics; various areas may contain disarticulated *iwi kūpuna* from this era; Kaka‘ako has areas where sediment contains disarticulated human remains from periods of high mortality due to epidemic; various locations of known and unknown burials throughout area; areas of fill may also contain *iwi kūpuna;* unauthorized and unmarked burials may be located at Kawaiaha‘o Cemetery, as it was regarded as a *pu‘uhonua*; Ala Moana Park said to have mass burial from smallpox epidemic;
6. *Limu*: Kaka‘ako was verified as a location to pick *limu* (*limu ‘ele ‘ele* was gathered in the location of where Pier 2 is today, which was a park next to the immigration depot); *‘opihi* and *hā‘uke‘uke* (*Colobocentrotus atratus*) also gathered in Kaka‘ako; *limu lipoa* and *limu waiwaiole* was gathered in Kaka‘ako, which would be added to poke; some interviewees were warned against collecting *limu* from areas in Kaka‘ako that may have motor oil in the water
7. Agriculture: rice paddies and *lo‘i kalo* (dry land variety) existed in the area for subsistence agriculture of local families; growing *kalo*, ti leaves, and sweet potato as well as raising pigs and chickens were common forms of subsistence living in Kaka‘ako; people grew *kalo* to make their own poi
8. *Pa‘akai*: Kaka‘ako verified as a location that one could obtain *pa‘akai* (salt)
9. Fishing: locations consist of Kewalo area, Kaka‘ako area, Fisherman’s Wharf, Ala Moana Park, Sea of Kuloloia, from Honolulu Harbor to Ala Moana Park, and open ocean off of Kaka‘ako; pole fishing, net throwing, torch fishing, spearing, and boat fishing; wide variety of fish and marine invertebrates caught in Kaka‘ako: *manini*, *mamo*, menpachi, *weke*, *‘upāpalu, kūmū, palani, uhu,* as well as squid, *tako,* and crab
10. Post-Contact Sites: *hale* of Kamehameha I located on the shore of Kuloloia as well as the fort and Wharf of James Robinson; European cemetery on King Street along Kawaiaha‘o to Mission Lane;
11. Demographics: Kaka‘ako had a dense population of displaced Hawaiians in mid-1800s; Honoakaha Housing Project was located where the Honolulu Brewery is located; Near the marshland of where Ala Moana Center was a community of nearly 90% Hawaiians called Ala Moana Hawaiian camp; Kaka‘ako was primarily a blue-collar community; Kaka‘ako became very ethnically diverse with Portuguese, Hawaiians, Japanese, Okinawan, Chinese, and Filipinos typically living in sub-communities (camps), though some areas, such as Magoon Block were mixed ethnicity communities

Elison & McElroy (2011:70-102)
12. Swamp area: the area that became Lewers & Cooke lumber yard; Ala Moana Park was previously swamp area; *mauka* of Ala Moana Mall were duck ponds and taro patches; beach leading to "Bowls" surf break was swamp; area that is now Sears was swamp and forest with no streets; Ala Moana Center was all marshland; the marshland had a lot of mud hens, ducks, and wild birds
13. Trails: there were many trails leading to the Ala Moana Park area
14. Transportation: bus and streetcar (also referred to as the trolley); people walked everywhere, since cars were not affordable for most Kakaʻako locals; the train was used by Kakaʻako locals, leaving from Aʻala to other areas of the island
15. Work: many Kakaʻako residents also worked in Kakaʻako, at such places as the City and County Road and Refuse Divisions (Incinerator), Honolulu Iron Works, and from home or relatives houses making *leis*
16: Housing: E.E. Black, Mr. Kamalae, Enoko Kealoha, and Jack Magoon were either property owners or property managers of many rental homes in Kakaʻako who primarily rented to Hawaiians; many Hawaiians rented in Kakaʻako; Dillingham, Castle & Cooke, and Ward owned most of Kakaʻako; tenement housing from Queen Street to Ala Moana Blvd.; Magoon Block had small residential cottages; Squattersville was behind the Incinerator; Don Ho lived in Squattersville; residential areas became commercial and industrial
17. Local Business: Piggly Wiggly's Super Market; Miwa Store; the animal hospital was on Kapiʻolani Blvd. (no name given); Honolulu Laundry; Lewers & Cooke lumberyard; Aiʻs gas station; Kodak Hawaii; KGMB station; horse stable and small racetrack at the end of Kawaiahaʻo; Kewalo Inn; potato chip factory; John Dominis Restaurant; Royal Brewery; Mexican Restaurant (no name given); Mi P.Y. Chong restaurant; Mr. Christian's restaurant; strip club between Ward and Piʻikoi Streets (no name given); Kewalo Theatre; American Sanitary Laundry; Primo Beer Company on Cooke and Kawaiahaʻo Streets; Honda Store
18. Houses of Worship: Kawaiahaʻo Church, Lamb of God Pentecostal Church; St. Agnes Church; Holy Ghost Church; Buddhist Temple
19. Recreation: open air theatre; Kewalo Theatre; Kakaʻako locals often camped in tents at Squattersville on the weekends; Mother Waldron Neighborhood Park sports (basketball, baseball, softball, football, volleyball); Mother Waldron Neighborhood Park live music on Saturday Nights; Thomas Square had tricycle races; swimming and surfing at various locations (Point Panic and Atkinson Drive); various children's games (broomstick games, walking on tin cans, tube rolling, sand bag games; picnicking;
20. Resources: property on Pensacola Street, next to McKinley High School had a stream with mullet as well as coconut trees; date trees on Queen Street; Kawaiahaʻo graveyard had many fruit trees, including mango and soursop; some Kakaʻako residents made alcohol out of pineapple and rice;
21. Community Events: Holy Ghost Days (Portuguese Catholic festival) put on by Holy Ghost Society, had a bazaar and sold malasadas; election season booths with food and entertainment at Ward and Waimanu Streets;
22. Music, Hula, & Kanikapila: many famous musicians hailed from Kakaʻako, including Aunty Genoa Keawe, Gabby Pahinui, Don Ho, Danny Kaleikini, and Chris Kamaka; Saturday Night Kanikapila at Mother Waldron Neighborhood Park; park near Pohukaina was where Portuguese gathered to sing harmonies together; Honolulu Girls Glee Club was a hula and music troupe led by Amelia Guerrero located in Kakaʻako
23. Neighborhood Culture: everyone was *ʻohana*; sharing was expected; respect for other's property and resources (e.g. no trespassing, no stealing; no collecting other's *limu*); Magoon block known for being very candid with each other; trusting neighbors was more common; blue-collar community; very ethnically diverse with Portuguese, Hawaiians, Japanese, Okinawan, Chinese, and Filipinos typically living in sub-communities (camps), though some areas, such as Magoon Block were mixed ethnicity communities; some friction between ethnicities and racism existed

Elison & McElroy (2011:70-102)
24. Changing Shoreline: much less freedom to access water and shorelines as Hawaiians did in pre-Contact era; shoreline was further out (by filling with rubbish); houses and coral gravel beaches where the Ilikai is located; shore had more boats and dry-docks; surfers go further out now; Ala Wai Canal was dredged and dredged material used for land fill; Ala Moana Beach Park had a lot of canoes parked on beach; Magic Island did not exist; Ala Wai Canal was clean before and people used to catch mullet in the channel; there were salt ponds along coast; more sandy beaches now; more crowded nowadays; the water was clear and clean until the City took over and then there was rubbish all over the reef; Fort Armstrong was located on the coast near Aloha Tower
25. World War II era: martial law was implemented; food was rationed out by the military using ration cards; the military took over Ala Moana Beach Park and the entire coastline for 3 years; access to marine food resources was next to impossible due to military rule over the coastlines; Kewalo Basin used for military vessels; military dumped swill into Kewalo basin, making the water very dirty; a military warehouse was located where the Hawaiian Electric building is near Aloha Tower; local Japanese not trusted, some taken to internment camps

4.3 Previous Traditional Cultural Properties (TCP) Study

A TCP Study was conducted by Kumu Pono Associates LLC for the proposed Honolulu Rapid Transit Project (HRTP), Sections 1-4 (Maly et al. 2013). Section 4 of the HRTP TCP Study covers Areas of Potential Effect (APE), consisting of lands in the proposed rail corridor, in the *ahupuaʻa* of Kalihi, Kapālama, Nuʻuanu, Honolulu, and Waikīkī in the District of Kona, Oʻahu Island (Figure 16). This portion of the TCP Study includes ethnographic research and oral historical interviews to augment earlier cultural studies covering HRTP APE lands stretching from Kalihi to Kālia, incorporating a wide range of historical literature including resources written in the Hawaiian language and accounts recorded by early visitors and residents. Much of the Historical literature in this study is cited in verbatim quotes with original context provided. Maly et al. (2013) based their study on the writings of early residents of the study area, native lore, 1848-1920s land tenure records, 1850-1930s surveys, 1860s-1920s Boundary Commission testimonies, land conveyance records, and historical narratives from the late 1700s to the 1920s describing these lands and her people. Hundreds of late 1700s to the early 1900s documents originally written in Hawaiian were translated by Maly et al. (2013), most of which were not previously accessible to the non-Hawaiian speaking public.

In order to guide the National Register eligibility evaluation process, The SRI Foundation (2013:20-30) summarized and categorized the Maly et al. (2013) findings into five themes:

1) Places where the gods and demigods walked the land;
2) Places of ceremonial importance, tribute sites, places associated with the dead and spirit world;
3) Notable events and individuals in Hawaiian history;
4) Places of traditional resource management; and
5) Trails and boundary markers.

According to The SRI Foundation (2013) a large number of these *wahi pana* and *inoa ʻāina* fit Criterion A and Criterion B of the official National Register Eligibility criteria provided in *How to Apply the National Register Criteria for Evaluation* (National Park Service 1995:2):

- Criterion A: That are associated with events that have made a significant contribution to the broad patterns of our history; or
- Criterion B: That are associated with the lives of persons significant in our past;
- Criterion C: That embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction; or
- Criterion D: That have yielded, or may be likely to yield, information important in prehistory or history

Table 12 provides a list of *wahi pana* and *inoa ʻāina* that lie within the Kakaʻako TOD Overlay project area and are recognized as eligible for the National Register according to The SRI Foundation's Section 4 Management Summary (2013:Tables 1 and 6). A series of maps exhibiting *wahi pana*, *iwi kūpuna*, and archaeological sites identified prior to and during the TCP Study and Archaeological Inventory Study (AIS) were also provided in Section 4 of the HRTP (SRI Foundation 2013: Appendix E-1 through E-4).

In addition, the TCP Study included an oral history and consultation component (Maly et al. 2013: Appendix D), which was prepared by Mina Elison (2013). This supporting document of the TCP Study includes insights from eight cultural informants regarding areas within Section 4 of the HRTP that were obtained via interview, email, or telephone (Elison 2013). Selected references to *inoa ʻāina* and *wahi pana* from interviews and other communications were provided in Elison (2013:10-13). Table 13 lists the references that pertain to areas within or adjacent to the Kakaʻako TOD Overlay project area.

Figure 16. TCP Study Project Corridor, Showing Section 4 (Courtesy of The SRI Foundation and Kumu Pono Associates LLC 2013).

Table 12. Maly et al. (2013) *Wahi Pana* and *Inoa ʻĀina* identified through Archival Research (adapted from The SRI Foundation 2013: Tables 1 & 6)

Maly et al. (2013)			
Name	**Description**	**National Register**	**Theme**
Hale Kauwila (House made of Kauwila wood) (see also Kauila)	Historical name given to area adjoining Pākākā and the old Fort, and the street which bears the name Hale Kauwila (Kuloloia shoreline section). The name was given to one of the large thatched structures built in the 1820s by the Chiefs, and was the place where the King, his Council, Governor/Judge Kekuanaʻoa, the Legislature, Board of Land Commissioners and many other offices of the Kingdom met. It was at this place that many of the major decisions of the Hawaiian Government were made (Ii 1959; Kamakau, 1961). It was this structure that gave rise to naming Hale Kauwila Street. (Register Map No.'s 241, 242, 864, 1910, 1955 and 2609). In another example, Brigham (1908:111) recounts an 1837 meeting that took place at Hale Kauwila ("council chamber"). The meeting involved the King, Kauikeaoluli (Kamehameha III), his sister Nahiʻenaʻena, his wife Kalama, Boki and other chiefs and representatives of France, England, and the United States. Hale Kauwila was a thatched house built of Kauwila wood. The rafters were taken from the sacred house of Līloa at Wai-pio, Hawaiʻi, a burial place of chiefs (Pukui et al. 1974) Kauila wood is associated with the akua Kū thus imbuing the Hale Kauwila with sacred qualities associated with the god.	**Criterion A**: Associated with pattern of traditional ceremonial use relating to governance; **Criterion B**: Associated with the akua Kū. Associated with historical figure King Kauikeaoluli (Kamehameha III)	2,3
Hale o Lono (House of Lono)	A heiau, and for a time, the residence of Liholiho (Kamehameha II), once situated at the area marked by the corner of Fort and Queen Streets. (Ii 1959; Rockwood 1957)	**Criterion A**: Associated with pattern of traditional ceremonial use; **Criterion B**: Associated with pattern of traditional ceremonial use	2,3
Honokaʻupu (Albatross Bay) (see also Kauanonoʻula)	A coastal land situated west of Kuloloia. Named for a chief and husband of Kauanonoʻula. The Hale Hui and Hale Kāʻili (houses of the gods) were situated here in the area between what is now Queen and Merchant Streets. The ancient trail from Waikīkī, joined the trail of Honuakaha and continued to Honokaʻupu, where a noted fresh water spring was situated, and continued on the ʻAiʻēnui. (Īʻī 1959, Rockwood 1957; Register Map No. 900)	**Criterion A**: Associated with pattern of traditional land use for transportation – trails. Associated with pattern of traditional resource use – spring water; **Criterion B**: Associated with chief Honokaʻupu	3, 4, 5

Maly et al. (2013)			
Name	**Description**	**National Register**	**Theme**
Honuakaha (Marked earth or Coastal land)	A land area bounded by Queen and Punchbowl Streets, once the site of an important coconut grove; former residence of Kinau (k.) father of Chiefess M. Kekauonohi. (Ii 1959; Rockwood, 1957; Māhele Claims 677, 680, 683 and 729; Register Map No.'s 241, 611 and 900). Property described in association with trails in the Kona District. "Let us return to where the trail from Waikīkī met the trail from Honuakaha, mauka of the Honokaʻupu spring." See Maly et al. (2013:106). Kekauonohi was a noted historical figure, granddaughter of Kamehameha I, married to Liholiho. See Maly et al. (2013:106).	**Criterion A**: Associated with pattern of traditional land use for transportation – trails; **Criterion B**: Associated with historical figures Kinau and Chiefess M. Kekauōnohi	3, 5
Hoʻokūkū (To compete)	Area between Honuakaha and Honokaʻupu, now covered by Queen Street. Healing heiau and a residence of Liholiho were situated here. (Ii 1959; Rockwood 1957). Property is associated with Liholiho (his residence), the trail between Kālia and Kukuluāeʻo, and the Papa *heiau* along the trail. See Maly et al. (2013:105).	**Criterion A**: Associated with pattern of traditional ceremonial use. Associated with pattern of traditional land use for transportation – trails; **Criterion B**: historical figure King Liholiho (Kamehameha II)	2, 3, 5
Kākāʻako (Strike and gather)	A land area, ancient fishing village and historic community, situated between Honuakaha and Kaholoakeāhole. In the historic period, a section of the land was used as a quarantine for plague victims. (Ii 1959; Rockwood 1957; Māhele Claims 3455 and 4457; Register Map No. 900). Property is named in the tradition of ʻAiʻai, son of Kūʻula (fish god). See Maly et al. (2013:59).	**Criterion B**: Associated with the *akua* ʻAiʻai, son of Kūʻula (fish god)	1
Kālia (Waited for)	An *ʻili* land of the coastal region of Waikīkī, noted for its numerous salt works and fishponds. "The trail from Kālia led to Kukuluaeo" (Ii 1959; Pukui et al. 1974; Māhele Claims 97 F.L., 100 F.L., 101 F.L., and 387; Register Map No.'s 111 and 1090). Property is associated with chief Hua-a-Kamapau and Kamehameha I (Maly et al. 2013:99).	**Criterion A**: Associated with pattern of traditional resource management. Associated with pattern of traditional land use for transportation – trails. **Criterion B**: Associated with the Chief Hua-a-Kamapau	1,2,3
Kaʻoaʻopa (meaning undetermined)	Coastal section of land between Mokuʻaikaua and Honuakaha. Area crossed by the trail from Honolulu to Kākāʻako and beyond, where attendants of Liholiho resided in the time of Kamehameha I. (Ii 1959; Rockwood 1957; Māhele Claims 19 and 129). See Maly et al. (2013:105).	**Criterion A**: Associated with pattern of traditional land use for transportation - trails	5

Maly et al. (2013)			
Name	**Description**	**National Register**	**Theme**
Kewalo (The calling)	A kula land and coastal region, noted for its fish and salt ponds. There was once a famous spring at Kewalo near the ponds, where victims of sacrifice at Kānelā'au Heiau on the slopes of Pū'owaina were first drowned. "The priest when holding the victims head under water would say to her or him on any signs of struggling, "*Moe malie i ke kai o ko haku.*" "Lie still in the waters of your superior." From this it was called "Kawailumalumai," "Drowning waters" The law under which the sacrifices were made, was called Kekaihehe'e. (Māhele Claims 97 F.L., 100 F.L., 101 F.L., 387, 1503, 1504 and 10605; Register Map No.'s 111, 611 and 1090).	**Criterion A**: Associated with pattern of traditional resource management. Associated with pattern of traditional ceremony relating to ritual sacrifice.	2,4
Kolowalu (An ancient law)	A section of land in Kukuluāe'o, and adjoining Kālia. During the reign of Kūali'i, the "Royal Kolowalu Statute" was declared for the "preservation of life," making it safe for people to travel the trails, and to be respectfully treated (Fornander 1917; Māhele Claim 3142; Register Map No.'s 111 and 1090) Kolowalu is connected by trails that cross Waikīkī and the Honolulu Region. See Maly et al. (2013:92).	**Criterion A**: Associated with pattern of traditional land use for transportation – trails; **Criterion B**: Associated with historical figure Chief Kūali'i	3,5
Kou (Cordia tree)	Said to be the ancient name of what is now called Honolulu. (Various features and named localities cited in traditions and historical accounts; Māhele Claims; and various Register Maps). Kou was noted for *kōnane* [Hawaiian checkers] and for *'ulu maika* [an ancient game likened to lawn bowling] and said to be named for the *Ilamuku* (executive officer) of Chief Kūkuhihewa of O'ahu. See Maly et al. (2013:7).	**Criterion A**: Associated with pattern of traditional ceremony relating to the Makahiki Seasonal ritual; **Criterion B**: Associated with historical figure Chief Kākuhihewa	2,3
Kō'ula (Red sugar cane)	Kō 'ula and Kewalo were lands which the ancient chief Hua, caused to be cultivated. Hua was known as a chief who cared for his people (S.M. Kamakau, 1865). Land section covering the Catholic burying ground and the Ward family's, "Old Plantation". Kō'ula is name given to lands cultivated by Hua. See Maly et al. (2013:52).	**Criterion B**: Associated with historical figure Chief Hua	3
Kukuluāe'o (The Hawaiian stilt)	A near shore land area in the Kākā'ako vicinity, traditionally a detached parcel belonging to Punahou of Waikīkī. "This was a famous place in ancient times, and the heiau was Pu'ukea" (Kamakau 1865). Noted for its fish and salt ponds. (Māhele Claims 97 F.L., 387, 982, 1503, 7712, 10463 and 10605; Register Map No.'s 111, 611, 1090 and 1471). Property is also linked with Hua-a-Kamapau, the chief of Honolulu/ Waikīkī, through reference to the Pu'ukea heiau. See Maly et al. (2013:82).	**Criterion A**: Associated with pattern of traditional ceremonial use. Associated with a pattern of traditional resource management; **Criterion B**: Associated with historical figure Chief Hua-a-Kamapau	2,3,4

Maly et al. (2013)			
Name	**Description**	**National Register**	**Theme**
Kuloloia (also written Kuloloio)	Once a beautiful sandy beach on the shore of Kou, and a favored residence of the high chiefess Nāmahana (wife of Ke'eaumoku, and mother of Ka'ahumanu and other significant figures in the Hawaiian Kingdom). There were a number of chiefly houses and heiau spread across the shoreline of Kuloloia, between Pākākā and Honuakaha. Nāmahana died at her home on the shore of Kuloloia, and "A younger cousin of Namahana's children, who was present at her death, was named Kuloloia for the place in which Namahana died." (Ii 1959; Rockwood 1957). Also named in tradition of 'Ai'ai, son of the fishing god Kū-'ula. See Maly et al. (2013:13).	**Criterion A**: Associated with pattern of traditional ceremonial use; **Criterion B**: Associated with historical figures: The high Chiefess Nāmahana wife of Ke'eaumoku, and mother of Ka'ahumanu. Associated with deity 'Ai'ai, son of the fishing god Kū'ula	1,2,3
Mauna Kilika (Silk Mountain)	Named for the mounds of silk cloth traded by foreigners in exchange for Hawaiian products. Area of the former residence of chief Kekuana'oa, Governor of O'ahu under Kamehameha III; and situated along the shore of Kuloloia. Area was later called Hale Kauwila, and is the source of the street with the same name (Register Map No. 900).	**Criterion B**: Associated with historical figure Chief Kekuana'oa, Governor of O'ahu	3
Pākākā (To skim, as stones over water)	Site of an ancient heiau of human sacrifice, dedicated to the god Kūho'one'enu'u (Westervelt 1915). Later the site of the Fort of Honolulu, and residence of chiefs. In the historic period, the site was developed into "Robinson" wharf on the western side of Hale Kauwila Street; and later filled in. (Ii 1959; P. Rockwood Map, 1957; and Register Map No.'s 241, 242, and 900).	**Criterion A:** Associated with pattern of traditional ceremonial use; **Criterion B**: Associated with the *akua* Kūho'one'enu'u	1,2
Pu'ukea (White hill) See also **Kukuluāe'o**	An ancient heiau built for or by, Hua-nui-ka-lā-la'ila'i, a hereditary chief of O'ahu, who was born at Kewalo (Kamakau 1865:22; Pukui & Ebert 1992). Also associated with the ancient Chief Luanu'u who was taken there when he was dying. See Maly et al. (2013:85).	**Criterion A:** Associated with pattern of traditional ceremonial use; **Criterion B**: Associated with historical figure Chief Hua-nui-ka-lā-la'ila'i and ancient Chief Luanu'u	2,3
Waikahalulu (Roaring water)	An *'ili* land, the upper section being where the goddess, Papa, embraced her husband Wākea, who was being taken to be sacrificed at Pākākā Heiau, and changed into the form of an *'ulu* (breadfruit tree). This *'ulu*, became known as the deity, Kāmeha'ikana, who had the power to overthrow governments. Kāmeha'ikana was a god called upon by Kamehameha I in his conquest of the islands (Kamakau 1991). The land area includes the section between Nu'uanu and Pauoa streams, and a section on the shore, below Hale Kauwila St., where it joins the sea at 'āina Hou, and adjoining Kuloloia and Ka'ākaukukui (Kamakau 1961; Māhele Claim of H. Kalama & Claim No.'s 7712, 11219 and 11225; Register Map No.'s 242, 244, 305, 611, 861, 900, 1090 &1471).	**Criterion B**: Associated with the *akua* Papa and Wākea, and the deity Kāmeha'ikana	1

Table 13. References to *Wahi Pana* and *Inoa ʻĀina* of Kakaʻako in Elison (2013)

Elison (2013)		
Name	**Comments**	**Informant**
Kākāʻako (Strike and gather)	• "...all of Kākāʻako is a "sensitive" area ..." (AK) • The song "Henehene Kou Aka" is about a courtship that took place during a bus ride that ends in Kakaʻako. (FG) • Kakaʻako was a place to collect *limu.* (FG) • Kakaʻako was marshy before development and people could hunt mudhens and other wild birds. (DL) • Kakaʻako had street festivals such as the Portuguese Holy Ghost Festival, fair events and food during election season (DL) (VD)(WH) • Kanikapila and various sporting events at Mother Waldron Neighborhood Park. (DL) • Graveyards and unmarked burials are encapsulated by fill in Kakaʻako. (DL)(WH) • Mother Waldron Park is an important sports and recreation hub for the Kakaʻako community. (DL)(VD) • There is high probability that *iwi kūpuna* will be encountered in the Kakaʻako area. (DS)(WH) • Kakaʻako had sand dunes in the distant past. (DS) • Kakaʻako in the 1940s had a large population of Hawaiians, but Portuguese, Asian, and Filipino working-class families also lived there (VD)(WH) • Incinerator was located at the John Dominis Restaurant in Kakaʻako (VD)(WH) • Thomas Park in Kakaʻako used to have tricycle races (VD) • Kawaiahaʻo Church in Kakaʻako was where people gathered to play Hawaiian music and hula (VD) • Many Hawaiian musicians and dancers hailed from and practiced in Kakaʻako (VD)(WH) • Residents of Kakaʻako kept small dry land sweet potato and *kalo* patches and pounded their own poi, they also grew ti for making *laulau.*(WH) • Squattersville was located in Kakaʻako Makai (WH) • Kawaiahaʻo Church in Kakaʻako was where families would spend some of their Sundays visiting buried relatives and relaxing. (WH) • Two theatres were important venues for Kakaʻako's community (WH) • A horse stable and small racetrack was once located in Kakaʻako (WH) • Some residents of Kakaʻako raised pigs and chickens (WH)	• Adrian Keohokalole (AK) • Francine Gora (FG) • Douglas Lapilio (DL) • Dexter Soares (DS) • Van Horn Diamond (VD) • William "Bill" Papaiku Haole, Jr.(WH)
Kālia (Waited for)	• Fishponds were located in Kālia, one of which supplied Kamehameha I with his favorite type of fish to eat. (PK) • Near Kālia was also Kamehameha's *loʻi* which he constructed and cared for while on Oʻahu. (PK) • Kaleikini ʻOhana lands in Kālia include Loko Kūwili, once adjacent to the Hawaiʻi Convention Center, but was dredged through in the construction of the Ala Wai Canal. (PK) • Kālia is the name of a region. The Ala Moana Shopping Center is located on a portion of Kālia. (DL) • A Hawaiian Camp was located in Kālia where the Ala Moana Shopping Center is located. (DL)	• Paulette Kaʻanohi Kaleikini (PK) • Douglas Lapilio (DL)

Elison (2013)		
Name	**Comments**	**Informant**
Kewalo (The calling)	• Japanese fished in Kewalo Basin and aku boats (sampan) moored in Kewalo Basin. (DL) • Various surf breaks exist along the south shore of Kewalo Basin. (WH) • Water was much cleaner than it is today at Kewalos. (WH) • Kewalo Inn, which served Hawaiian and local food, was located on the property that Ward Center is now located. (WH)	• Douglas Lapilio (DL) • William "Bill" Papaiku Haole, Jr.(WH)
Kou (Cordia tree)	• The song "Henehene Kou Aka" is about a courtship that took place during a bus ride from Kalihi to Kakaʻako, passing through Kou. (FG)	• Francine Gora (FG)
Kukuluāeʻo (The Hawaiian stilt)	• The area in which Puʻukea Heiau once stood. (PK) • Location of Kukuluāeʻo pointed out on map. (RF)	• Paulette Kaʻanohi Kaleikini (PK) • Randie Fong (RF)
Pākākā (To skim, as stones over water)	• Several heiau which date to the 1500s were located in Honolulu, including Pākākā Heiau, which was located at the foot of Fort Street in downtown Honolulu. (• Within the vicinity of Pākākā Heiau was an *aliʻi* complex which also served as the residence of Kamehameha I from 1809-1812.	• Paulette Kaʻanohi Kaleikini (PK) • Randie Fong (RF)
Puʻukea (White hill)	• Puʻukea Heiau was located in the area of Kukuluaeo which is now the location near Halekauwila and Cooke Streets. Most likely named after the *heiau* respective ʻili of the same name, Puʻukea. Kaleikini traces her lineage to the chief who is associated with the construction of this heiau.	• Paulette Kaʻanohi Kaleikini

4.4 IDENTIFIED CULTURAL GROUPS, PRACTICES, AND RESOURCES SUMMARY

Numerous cultural groups, practices, and resources were identified by Wilson Okamoto and Associates, Inc. (2002), Spearing et al. (2008), Vogeler et al. (2010), Genz and Hammatt (2010), Elison and McElroy (2011), Maly et al. (2013), and Elison (2013) for the Kakaʻako TOD Overlay project area. In general, cultural groups included Native Hawaiians as well as a few *kamaʻāina* and cultural practitioners belonging to various ethnic groups and groups of mixed ethnicities. Cultural practices identified in the CIAs and TCP Study consisted of a number of traditional Hawaiian activities as well as activities that bind other cultural and ethnic groups together. In general, traditional Hawaiian activities were not reported as currently being practiced in a traditional context, perhaps due to drastic environmental changes and large-scale development, yet some survive and other cultural groups have developed unique cultural practices in the wake of urban development. These reviewed reports demonstrate that in the distant past, there was an abundance of tangible cultural resources, such as an array of fish, plants, salt, and ceremonial sites in the project area. Currently, some of those resources are available in a handful of locations, but far less in quantity. However, intangible resources are still felt by Native Hawaiians who identify with these *wahi pana,* as *moʻolelo* and ceremonial practices imbue the cultural landscape with the *mana* of their ancestors. Further, the presence of archaeological sites and *iwi kūpuna* in these lands is well documented. In contrast, non-traditional Hawaiian cultural resources were also being utilized by various cultural groups during these assessments, such as the *aku sampan* and memorials to Historic figures of Kakaʻako.

4.4.1 Identified Cultural groups

A total of 200 cultural groups, practitioners, and informants were identified between the five previously conducted CIAs and TCP Study. No cultural groups or individuals were identified in Wilson Okamoto and Associates, Inc. (2002). However, out of the 81 community members identified by Spearing et al. (2008), they received responses from 34 individuals and were able to interview 12 informants, which were comprised of residents, cultural and lineal descendents, and cultural practitioners. Twenty individuals were identified by Vogeler et al. (2010) and interviewed five out of the ten respondents. Genz and Hammatt (2010) identified 39 potential informants, consisting of community members, government agency officials, community organization representatives, cultural and lineal descendants, cultural practitioners, and residents. Six individuals of 16 respondents were interviewed for the CIA. Elison and McElroy (2011) identified 88 cultural groups and individual informants, with a total of 8 individuals participating in interviews. Elison (2013) included transcripts from 6 newly conducted ethnographic interviews, transcripts from two previously conducted ethnographic interviews (Elison and McElroy 2011), a telephone consultation summary, and information from an email consultation in the Oral History-Consultation Interview Program component of the TCP Study. Table 14 provided below lists the cultural groups, practitioners, and informants identified by the previously conducted CIAs. Appendix D provides a list of all cultural informants contacted in the previously conducted CIAs and contact logs summarizing communications between CIA preparers and informants.

Of the 200 cultural practitioners, groups, and informants identified, the grand majority were Native Hawaiians. Very few individuals representing other ethnic and cultural groups were identified or contacted for these studies.

Table 14. Cultural Groups, Practitioners, & Informants Identified in Reviewed CIA & TCP

Name	Affiliation	CIA Identifying informants	Participated
Abord, Chelsie	Cultural informant recognized by KD	Elison and McElroy (2011)	No
Agard, Louis	Former fisherman in Kewalo Basin	Spearing et al. (2008); Vogeler et al. (2010); Genz & Hammatt (2010)	Yes
Ahahui, Kaʻahumanu Society	Cultural informants recognized by KD	Elison and McElroy (2011)	No
Ailā, William	Hui Mālama I Na Kūpuna O Hawaiʻi Nei	Spearing et al. (2008); Vogeler et al. (2010); Genz & Hammatt (2010)	Yes
Alves, Henry	Former resident of Kakaʻako 1923-1941 and Participant in the 1978 University of Hawaiʻi Oral History Study: *Remembering Kakaʻako 1910-1950.*	Spearing et al. (2008); Genz & Hammatt (2010)	Yes
Apaka, Jeff	Waikiki Community Center Kūpuna	Genz & Hammatt (2010)	No
Apo, Peter	Hawaiian Cultural Consultant; MVE Pacific—Architects for Kakaʻako Makai Master Plan	Spearing et al. (2008); Vogeler et al. (2010); Genz & Hammatt (2010)	No
Arcalas, Cara	Cultural informant recognized by KD	Elison and McElroy (2011)	No
Ayau, Eddie Halealoha	Cultural informant recognized by KD	Elison and McElroy (2011)	yes
Ayau, Peter	Hui Mālama I Na Kūpuna O Hawaiʻi Nei	Vogeler et al. (2010)	No
Bates, Keʻala	Cultural informant recognized by KD	Elison and McElroy (2011)	No
Bacon, Pat Namaka	Bishop Museum Archives	Genz & Hammatt (2010)	No
Becket, Jan	Photographer of sacred sites	Vogeler et al. (2010)	No
Bosley, Bob	Diamond Head Sprinkler Company	Spearing et al. (2008)	No
Brown, Desoto	Bishop Museum Archives	Genz & Hammatt (2010)	No
Burke, Jackie Kahoʻokele	KAHEA	Vogeler et al. (2010)	No
Cayan, Phyllis "Coochie"	SHPD History and Culture Branch Chief; Cultural informant recognized by KD	Spearing et al. (2008); Vogeler et al. (2010); Elison and McElroy (2011)	Yes; referrals
Cazimero, Kanoe	Kawaiahaʻo Church Archives & Cemeteries Na Iwi Committee	Genz & Hammatt (2010); Vogeler et al. (2010)	No
Center for Oral History, UH Mānoa	Cultural informants recognized by KD	Elison and McElroy (2011)	No
Ching, Baron	Kahu for Kaniakapupu— Kauʻikeaouli's Summer Palace	Vogeler et al. (2010)	No
Chun Oakland, Suzanne	Hawaiʻi State Senator, Representing 13th District	Vogeler et al. (2010)	Yes
Confidential	Kamaʻāina of Kakaʻako	Genz & Hammatt (2010)	No
Cruz, Lynette	President, Ka Lei Maile Aliʻi Hawaiian Civic Club	Vogeler et al. (2010)	No
DaMate, Leimana	ʻAha Kiole member, father raised in Kakaʻako	Spearing et al. (2008)	No
Dang, Mike	Kewalo Development	Spearing et al. (2008)	No
Dawson, Beadie Kanahele	Played at Mother Waldron Neighborhood Park as a child; former Land attorney for the State of Hawaiʻi and City Planning Commission; practitioner of *hoʻoponopono*	Elison (2013)	Yes
Del Toro, Rachel & Samuel	Cultural informants recognized by KD	Elison and McElroy (2011)	No

Name	Affiliation	CIA Identifying informants	Participated
Diamond, Van Horn	Cultural Descendant; Cultural informant recognized by KD & SHPD	Spearing et al. (2008); Elison and McElroy (2011); Elison (2013)	Yes - Elison & McElroy (2011) and Maly et al. (2013)
Downing, George	Save our Surf	Genz & Hammatt (2010)	No
D'Olier, Mitch	Former manager of the Victoria Ward Estates.	Spearing et al. (2008)	No
Enomoto, Stanton	Office of Hawaiian Affairs, Special Assistant to the Administrator	Spearing et al. (2008)	No
Falemei, Hinaleimoana	Cultural informant recognized by SHPD; Oʻahu Island Burial Council, Vice-Chair	Elison and McElroy (2011)	Yes
Faulkner, Kiersten	Historic Hawaiʻi Foundation	Spearing et al. (2008); Genz & Hammatt (2010)	Yes
Flores, George Kahumoku	Member, Ka Lei Maile Aliʻi Hawaiian Civic Club	Vogeler et al. (2010)	No
Fong, Randie	Cultural informant from Kalihi with knowledge of Honolulu area	Elison (2013)	Yes
Freitas, Bob	Planner, Department of Hawaiian Homelands	Spearing et al. (2008)	No
Frierson, Jim	Kakaʻako Coalition, Kakaʻako small business owner	Spearing et al. (2008); Genz & Hammatt (2010)	No
Furushima, Scottie	Kewalo Keiki Fishing Conservancy	Genz & Hammatt (2010)	No
Galuteria, Brickwood	Raised in Kakaʻako	Spearing et al. (2008)	No
Garcia, Clifford	Longtime business owner of Tropical Lamp & Shade Co.	Spearing et al. (2008)	Yes
Gomes, Phoebe	Cultural informant recognized by KD	Elison and McElroy (2011)	No
Gomes, Robin	Cultural informant recognized by KD	Elison and McElroy (2011)	No
Gora, Francine	Na Kūʻauhau ʻo Kahiwa Kanekapolei, Koʻolaupoko Hawaiian Civic Club	Elison (2013)	Yes
Grace, Nadine K. (Takaki)	Cultural informant recognized by KD	Elison and McElroy (2011)	No
Graff, Gwendolyn Y.	Cultural informant recognized by KD	Elison and McElroy (2011)	No
Guila-Theone, Nicole (Kaleikini)	Cultural Descendant	Spearing et al. (2008); Elison and McElroy (2011)	Via PK
Haʻi ʻOhana	Cultural informants recognized by KD	Elison and McElroy (2011)	No
Hale o Na Aliʻi o Hawaiʻi, Harriet Smith	Cultural informant recognized by KD	Elison and McElroy (2011)	No

Name	Affiliation	CIA Identifying informants	Participated
Haole, William Boysie P. III	Cultural informant recognized by KD	Elison and McElroy (2011); Elison (2013)	Referrals
Haole, William P. Jr.	Cultural informant recognized by KD	Elison and McElroy (2011)	No
Haili's Hawaiian Food	Long-time tenant in the Ward Farmer's Market	Spearing et al. (2008)	No
Hedlund, Nancy	Secretary, Ala Moana/Kakaʻako Neighborhood Board	Spearing et al. (2008); Genz & Hammatt (2010)	No
Higgins, Colette	Hawaiian historian, specializing in Queen Kapiʻolani, Kapiʻolani Girls' Home and the Kakaʻako Branch Hospital	Spearing et al. (2008); Genz & Hammatt (2010)	No
Hughes, Claire	Mother grew up in Kakaʻako	Spearing et al. (2008); Genz & Hammatt (2010)	Yes
Hui Malama I Na Kupuna o Hawaiʻi Nei, William Aila	Cultural informant recognized by KD	Elison and McElroy (2011)	No
Huihui, Henry	Family were former residents of Kakaʻako	Spearing et al. (2008)	No
Huihui, Micky	Hālau Kū Māna	Genz & Hammatt (2010)	No
Hustace, Cedric	Descendant of Victoria Ward.	Spearing et al. (2008)	No
Iwami, Ron	Friends of Kewalos	Genz & Hammatt (2010)	Yes
Iopa, Rob	President, WCIT Architecture	Spearing et al. (2008)	No
Jones, Bob	Writer for Midweek Press	Spearing et al. (2008)	Yes
Kaʻaihue, Isaac	Cultural informant recognized by Keala Pono	Elison and McElroy (2011)	No
Kahn, Leimomi	Kamaʻāina	Spearing et al. (2008); Genz & Hammatt (2010)	Yes
Ka Hui O Malama Kakaʻako Paka	Local organization	Genz & Hammatt (2010)	No
Kai, Carole	McKinley High School alumnus, Carole Kai Charities	Vogeler et al. (2010)	No
Kai Makana	Local organization	Genz & Hammatt (2010)	No
Kaleikini, Aliʻikaua	Cultural Descendant	Spearing et al. (2008)	Via PK
Kaleikini, Kala W.	Cultural Descendant	Spearing et al. (2008)	Via PK
Kaleikini, Noʻeau	Cultural Descendant	Spearing et al. (2008)	Via PK
Kaleikini, Paulette	Recognized descendant of Kakaʻako; Kaleikini ʻOhana as cultural informants recognized by KD	Spearing et al. (2008); Elison and McElroy (2011)	Yes - only in Spearing et al. (2008)
Kaleikini, Tuahine	Cultural Descendant	Spearing et al. (2008)	Via PK
Kapanui, Lopaka	Mysteries of Honolulu, Famous storyteller, folklorist	Spearing et al. (2008); Vogeler et al. (2010)	Yes

Name	Affiliation	CIA Identifying informants	Participated
Kaopuiki, Pi‘ilani	McKinley High School alumnus	Vogeler et al. (2010)	Yes
Kamae, Eddie & Myrna	Cultural informants recognized by Keala Pono	Elison and McElroy (2011)	No
Kamai, May	Cultural informant recognized by Keala Pono	Elison and McElroy (2011)	Yes
Kamaka, Fred Sr. & Sam Jr.	Cultural informants recognized by Keala Pono	Elison and McElroy (2011)	No
Kapua, Charles	Member of Pearl Harbor Hawaiian Civic Club; Mr. Kapua’s grandfather owned a fish market in Kaka‘ako; Kama‘āina of Kewalo Ahupua‘a	Spearing et al. (2008); Vogeler et al. (2010); Genz & Hammatt (2010)	Yes
Keahiku, Carter Leland	Cultural informant recognized by KD	Elison and McElroy (2011)	No
Keana‘aina, Betty	Cultural Descendant	Spearing et al. (2008), Elison and McElroy (2011)	No
Keana‘aina, Luther	Cultural Descendant	Spearing et al. (2008)	No
Keana‘aina, Kihei	Cultural informant recognized by KD	Elison and McElroy (2011)	No
Keana‘aina, Michelle	Cultural informant recognized by KD	Elison and McElroy (2011)	No
Keana‘aina, Noelani Luther	Cultural informant recognized by KD	Elison and McElroy (2011)	No
Keana‘aina, Vicky	Cultural informant recognized by KD	Elison and McElroy (2011)	No
Keana‘aina, Wilsam	Cultural Descendant	Spearing et al. (2008)	No
Keaweaheulu, Joseph M.	Cultural informant recognized by KD	Elison and McElroy (2011)	No
Kekaula, Mary Kualoku	Cultural informant recognized by KD	Elison and McElroy (2011)	No

4.4.2 Cultural Practices & Resources Identified

The background and community consultations sections of Spearing et al. (2008), Vogeler et al. (2010), and Genz & Hammatt (2010) revealed a number of cultural practices that have occurred and/or are currently occurring in the Kakaʻako TOD project area. Table 15 provides a compilation of cultural practices identified in the previously conducted CIAs. As with other sections of these CIAs, a very comprehensive attempt at identifying past and present cultural practices and resources of Native Hawaiian groups was made. However, those of other ethnic groups and groups united by non-traditional Hawaiian cultural practices were scarcely covered. Further, the scope of each report was limited to the project area's boundaries. Therefore, cultural practices and resources, such as those listed in Table 8, occurring outside of the project areas of the previously conducted reports, but within and adjacent to the Kakaʻako TOD project area, still need to be identified and assessed.

Table 15. Cultural Practices & Resources Identified in Reviewed CIA

Practice/Resource	Practice/Resource Area	Time Period	Cultural Group	CIA Identifying Cultural Practice
Agriculture (*loʻi kalo, niu,* & non-traditional; animal husbandry)	Various locations within project area	Pre-Contact to Historic	Hawaiians (no longer practiced in area); Ward Family (no longer practiced); Kakaʻako residents (small scale subsistence & supplemental agriculture); Hālau Kū Māna (diverse array of native Hawaiian plants for education & traditional use)	Wilson Okamoto and Associates, Inc. (2002); Spearing et al. (2008); Vogeler et al. (2010); Genz & Hammatt (2010); Elison and McElroy (2011)
Aquaculture, fishponds (*loko iʻa*)	Makai areas of Kakaʻako & Kewalo	Pre-Contact to Historic	Hawaiians (no longer practiced in area)	Spearing et al. (2008); Vogeler et al. (2010); Genz & Hammatt (2010)
Archaeological Sites	Various locations within project area (in marked & unmarked locations)	Pre-Contact to Present	Hawaiians, other ethnic groups, & Community members (no specific ethnic group)	Spearing et al. (2008); Vogeler et al. (2010); Genz & Hammatt (2010)
Cemeteries & burials (*iwi kūpuna*), traditional Hawaiian & post-Contact	Various locations within project area (in marked & unmarked locations)	Pre-Contact to Historic	Pre-Contact & early Contact Hawaiians (no longer practiced); Historic era no specific ethnic group	Spearing et al. (2008); Vogeler et al. (2010); Genz & Hammatt (2010)
Canoe landing & boat moorage	Kewalo Basin	Pre-Contact to Historic (canoe); Historic to present (boat)	Hawaiians (canoe landing no longer practiced in area); boat moorage practiced by various commercial, cultural, & ethnic groups	Genz & Hammatt (2010)
Ceremony & Religious Congregation	Various locations within project area	Pre-Contact to Present	Hawaiians (no longer practicing at *heiau;* human sacrifice abandoned; Catholic Church groups (Annual Holy Ghost Ceremony)	Spearing et al. (2008); Vogeler et al. (2010); Genz & Hammatt (2010)
Feasting (*lūʻau*) & traditional food preparation (*aku* drying)	Kewalo Basin area	Undeter-mined to Present	Hawaiians & other ethnic groups	Vogeler et al. (2010); Genz & Hammatt (2010)
Fishing (net & pole)	Kewalo Basin & Ala Moana areas (shoreline & from boats)	Pre-Contact to Present	Fishermen (no specific ethnic group)	Vogeler et al. (2010); Genz & Hammatt (2010)
Fishing, *aku sampan*	Kewalo Basin area	Historic to Present	Fishermen of the *Kula Kai*, last remaining *aku sampan* at Kewalo Basin	Genz & Hammatt (2010)
Fish processing & canning	Kewalo Basin area	Historic	Local, mostly Japanese, Korean, & Filipino	Genz & Hammatt (2010)

Practice/Resource	Practice/Resource Area	Time Period	Cultural Group	CIA Identifying Cultural Practice
Fisherman's Wharf	Bounded by Ala Moana Blvd., Ward Ave., & Kewalo Basin	Historic to Recent years	Community members (no specific ethnic group); tourist & local patrons	Spearing et al. (2008)
Habitation	Various locations within project area	Pre-Contact to Present	Hawaiians & other ethnic groups; modern era no specific ethnic group	Spearing et al. (2008); Vogeler et al. (2010); Genz & Hammatt (2010)
Historic Buildings	Various locations within project area	Historic to present	Community members (no specific ethnic group); commercial groups & individuals	Spearing et al. (2008); Vogeler et al. (2010); Genz & Hammatt (2010)
Memorial statue of Mother Marianne Cope	Kakaʻako Waterfront Park	Modern/ Present	Community members (no specific ethnic group)	Genz & Hammatt (2010)
Memorial statue of the *Pueo ʻAumākua*	Kakaʻako Waterfront Park	Modern/ Present	Community members (no specific ethnic group)	Genz & Hammatt (2010)
McKinley High School & Memorial statue of President William McKinley	Bound by King St., Pensacola St., Kapiolani St., & Neal S. Blaisdell Center	Historic to present	Community members (no specific ethnic group); current students & alumni	Vogeler et al. (2010)
Mother Waldron Neighborhood Park	Bounded by Halekauwila St., Coral St., Pohukaina St., & Cook St.	Historic to present	Community members (no specific ethnic group)	Spearing et al. (2008); Vogeler et al. (2010);
Plant & *limu* gathering for traditional purposes	Various locations within project area; McKinley High School campus	Pre-Contact to Present	Practitioners of *lāʻau lapaʻau;* gatherers of *pili* & *mahiki* grass (no longer practiced in area)*; limu* for traditional dishes	Spearing et al. (2008); Genz & Hammatt (2010)
Quarantine, human & animal	Kakaʻako Makai	Historic	Past smallpox, cholera, bubonic plague, & leprosy victims (no specific ethnic group); domesticated animals (pets & livestock)	Spearing et al. (2008); Vogeler et al. (2010); Genz & Hammatt (2010)
Arms storage, & practice; coastal defense	Kakaʻako Makai	Historic	U.S. Army & Honolulu Rifle Association	Spearing et al. (2008); Vogeler et al. (2010); Genz & Hammatt (2010)
Salt (*paʻakai*) gathering & production (*kai hoʻolulu*)	Much of Kakaʻako & Kewalo	Pre-Contact to Historic	Hawaiians, other ethnic groups, & commercial groups	Spearing et al. (2008); Vogeler et al. (2010); Genz & Hammatt (2010)
Surfing/Body Surfing & Swimming	*Makai* of Kewalo Basin and Kakaʻako Waterfront Park	Pre-Contact to Present	Surfers/Body Surfers, (no specific ethnic group)	Spearing et al. (2008); Genz & Hammatt (2010)

Practice/Resource	Practice/Resource Area	Time Period	Cultural Group	CIA Identifying Cultural Practice
Trails (*ala hele*)	Leading from Waikīkī to Honolulu (Kou) & connecting various communities to each other & resources	Pre-Contact to Present	Hawaiians, other ethnic groups, & Community members (no specific ethnic group)	Spearing et al. (2008); Vogeler et al. (2010); Genz & Hammatt (2010)
Storied Places (*wahi pana*) & spiritual land associations	Various locations within project area	Pre-Contact to Present	Hawaiians, other ethnic groups, & Community members (no specific ethnic group)	Spearing et al. (2008); Vogeler et al. (2010); Genz & Hammatt (2010)
Ward Farmer's Market	Bound by Auahi St., Ward Ave., Queen St., & Kamakee St.	Historic to present	Community members (no specific ethnic group)	Spearing et al. (2008)
Waste Management, Historic era	*Makai* areas of Kaka'ako & Kewalo	Historic	Public & municipal	Spearing et al. (2008); Vogeler et al. (2010); Genz & Hammatt (2010)

5.0 NEWLY IDENTIFIED CULTURAL RESOURCES

Due to the fact that the Kaka'ako Transit Oriented Development (TOD) project area is spatially larger than the project areas of the previously conducted Cultural Impact Assessments (CIAs), there were several areas not covered by these assessments (Figure 17). Further, cultural resources were not identified for areas adjacent to the previous CIA project areas, which are to be included in these assessments according to the official CIA guidelines (OEQC 1997).

A number of cultural practices and resources that were either overlooked or outside of the scope of previous CIAs were identified in the course of this SCIA that occur in or adjacent to the Kaka'ako TOD Overlay project area. Further, cultural resources valued by non-Traditional and non-ethnic based cultural groups were considered in this assessment, as contemporary Kaka'ako is a community of multiple cultures and a hub for cultural activities for the entire island community.

Figure 17. Kaka'ako TOD and Reviewed CIA Project Areas.

Cultural resources have been grouped as: Historic Places and Landmarks, Cultural Learning Facilities, Public Parks and Grounds, Memorials and Commemorations, Religious and Spiritual Gathering Places, and Public Art Installation and Entertainment Centers. These locations function as cultural resources in a sense that community members frequent them tap into the institutional knowledge held by members of the same cultural group or sub-group who also frequent the location in addition to the resource (i.e. memorials, art, music, and food) that they identify with. Further, regular and intermittent gatherings by those united by a common tradition, practice, ideal, identity, belief, and/or memory generates an institutional knowledge within the group and serves to perpetuate their cultural practices and values. In some cases, cultural resources are not necessarily tangible in nature, but are locations that serve as repositories for various shared traditions, practices, ideals, identities, beliefs, and memories.

For the Kaka'ako TOD Overlay SCIA, numerous community consultations were performed, which focused on several different types of cultural groups representing the cultural landscape of the area that is now considered Kaka'ako. Cultural groups identified for the SCIA consisted of groups united by ethnicity, religion and spirituality, memorials, arts and entertainment, as well as sports and recreation. A total of 78 cultural groups and cultural informants were contacted for consultation, 29 of which agreed to participate. Participation consisted of 5 referrals to other informants, 7 email communications providing information on cultural resources, 2 informants granting permission to use prior interview data for Kaka'ako, 9 online questionnaire submittals, and and 6 interviews. However, one interview was not included as the cultural resource was to be discontinued and one online questionnaire was retracted.

In addition to documentation research and community consultations, five site inspections were performed on the 27th July as well as the 2nd, 10th, 15th, and 22nd of August 2013 by Kimberly M. Mooney of Pacific Legacy, Inc. to determine the extent of cultural usage of the property. These inspections consisted of largely of pedestrian survey and photographic documentation of portions of the project area. The area designated as Kaka'ako Makai and the HECO Downtown Power Plant portion of the Kaka'ako TOD Overlay project area were investigated on 27 July and 15 August 2013. Portions of the area designated as Kaka'ako Mauka was investigated on the 2nd, 10th, 15th, and 22nd of August 2013, sweeping streets generally from *mauka* to *makai* and 'Ewa to Diamond Head.

A total of 34 cultural resources consisting of Historic Places and Landmarks (n=8), Cultural Learning Facilities (n=7), Public Parks and Grounds (n=7), Memorials and Commemorations (n=4), Religious and Spiritual Gathering Places (n=4), and Public Art Installation and Entertainment Centers (n=4) were identified in this assessment (Figure 18; Table 16). A significant number of cultural resources (n=21) were identified as occurring within the project area and numerous resources occurring in areas adjacent to project area (n=13). Many of these cultural resources are unique locations where events and activities that are vital to various cultural groups are held. While some groups (e.g. contemporary and urban arts groups and the LGBT community) are often discounted by cultural studies due to their contemporary and/or "sub-culture" nature they exhibit all of the hallmarks or a distinct cultural group. Thus, it seems necessary to fully assess what cultural impacts may be caused by the proposed Kaka'ako TOD project, if it is enacted.

Newly Identified Cultural Resources:

1 Hawai'i Capitol Historic District
2 HECO Downtown Plant
3 Aloha Tower Complex
4 Falls of Clyde
5 Mabel Smyth Memorial Building
6 Post Office, Customhouse, & Courthouse Building
7 Dillingham Transportation Building
8 U.S. Immigration Office
9 African American Diversity Cultural Center of Hawai'i
10 Diverse Art Center
11 Hawai'i Children's Discovery Center
12 Maritime Museum
13 Nā Mea/Native Books Hawai'i
14 The Refuge (808 Urban)
15 Home of the Brave Tour
16 Kaka'ako Waterfront Park
17 Kewalo Basin Park
18 Kaka'ako Makai Gateway Park
19 Mother Waldron Neighborhood Park
20 Ala Moana Beach Park
21 Irwin Park
22 Thomas Square
23 Ehime Maru Memorial
24 MADD Memorial
25 Nagasaki Peace Bell
26 Florentino Das Plaque
27 First Chinese Church of Christ
28 Kawaiaha'o Church
29 Ke Alaula Oka Malamalama
30 Makiki Christian Church
31 POW! WOW!
32 Neal S. Blaisdell Complex
33 FreshCafe & Loft in Space
34 Vacant Lots & Thoroughfares

Figure 18. Map of Newly Identified Cultural Resouces (adapted from Google Earth map).

Table 16. Newly Identified Cultural Resources (map location numbers correspond with Figure 18).

Map Location	Resource	Resource Area	Period & Frequency	Comments
Historic Places & Landmarks				
1	Hawai‘i Capitol Historic District	57 acre area includes: 20 Historic Structures	1794 - present	Located partially within and adjacent to project area. Includes: Kawaiaha‘o Church, Hawaiian Mission Houses, Kapuāiwa Building, Hawai‘i State Library, Honolulu Hale, Honolulu Hale Annex (Mission Memorial Building Complex), and State (Territorial) Office Building. These structures are in or adjacent to the project area.
2	Hawaiian Electric Company (HECO) Downtown Plant	222 Ala Moana Boulevard	1929 - present	Architectural resource; in project area
3	Aloha Tower (State Site No. 80-14-9929), Aloha Tower Marketplace & Entertainment Complex	Pier 9, Honolulu Harbor	1926 - present	Architectural resource and Historic events relating to Hawaiian history ; adjacent to project area
4	The *Falls of Clyde*	Pier 7, Honolulu Harbor	Ship 1878-present, (in repair)	Maritime and Historical resource; adjacent to project area; No estimated date of reopening
5	Mabel Smyth Memorial Building	corner of Punchbowl St.& Ala Moana Blvd.	1941 - present	Architectural resource and Historic events relating to Hawaiian medical history; in project area
6	Post Office, Customhouse, and Courthouse Building (King David Kalākaua Building)	335 Merchant Street across Punchbowl Street from the project area’s western boundary	1922 - present	Architectural resource and Historic events relating to Hawaiian history ; adjacent to project area
7	Dillingham Transportation Building	*makai* end of Bishop Street, across from the HECO Downtown	1929 – present	Architectural resource and Historic events relating to Hawaiian history ; adjacent to project area
8	U.S. Immigration Office	595 Ala Moana Boulevard	mid-1930s - present	Architectural resource and Historic events relating to Hawaiian history ; adjacent to project area
Cultural Learning Facilities				
9	African American Diversity Cultural Center of Hawai‘i (AADCCH)	1311 Kapiolani Blvd Ste 203	Modern/ present	In project area
10	Diverse Art Center	1034 Queen Street	Modern/ present	In project area
11	Hawai‘i Children’s Discovery Center	111 Ohe Street	Modern/ present	In project area
12	Maritime Museum	Pier 7, Honolulu Harbor	1988-2009	No estimated date of reopening; adjacent to project area
13	Nā Mea/Native Books Hawai‘i	1050 Ala Moana Blvd, Suite #1000	Modern/ present	In project area
14	The Refuge (808 Urban)	683 Auahi Street	Modern/ present	In project area
15	Home of the Brave Tour	Waimanu Street	Modern/ present	In project area
Public Parks and Grounds				
16	Kaka‘ako Waterfront Park (major venue for various cultural activities & events)	Bound by Pier 1 complex; John Burns School of Medicine Campus; Kelikoi St., & Kewalo Basin	Intermittent use	In project area; includes the surf breaks Point Panic, Flies, & Incinerators; fishing and diving, takes place along entire coastline (various fish species)
17	Kewalo Basin Park (significant venue for various cultural activities & events)	End of Kewalo Basin access road, between sea wall & harbor	Intermittent use	In project area; various marine activities associated with coastline of park, including fishing and surfing; harbor is moorage for dinner cruzes, parasailing, commercial fishing, glass bottom boats, and jetski rentals
18	Kaka‘ako Makai Gateway Park (significant venue for various cultural activities & events)	Bound by Cooke St., Ala Moana Boulevard, & Ohe St	Intermittent use	In project area; various activities,from organized events to random usage
19	Mother Waldron Neighborhood Park (significant venue for various cultural activities & events)	525 Coral St.	1937-present; Intermittent use	Site#80-14-1388; a “C & C of Honolulu Art Deco Park"; Within project area; from numerous regularly occurring activities, to major annual events, to random usage of park
20	Ala Moana Beach Park (major venue for various cultural activities & events)	Bound by Kewalo Basin, Ala Moana Boulevard, Ala Wai Harbor, & ocean.	Historic-present; Intermittent use	Adjacent to project area; from numerous regularly occurring activities, to major annual events, to random usage of park
21	Irwin Park (minor venue for various cultural activities & events)	Bound by Aloha Tower Dr., Bishop St., Ala Moana Boulevard, & Fort St.	1930-present; Intermittent use	Adjacent to project area; random usage of park, possible small scale regular usage
22	Thomas Square (minor venue for various cultural activities & events)	925 S Beretania St.	Intermittent use	Adjacent to project area; from numerous regularly occurring activities, to major annual events, to random usage of park
Memorials and Commemorations				
23	Ehime Maru Memorial	Kaka‘ako Waterfront Park	2002-present	Tragic sinking of a Japanese educational fishing vessel in 2001; in project area

Map Location	Resource	Resource Area	Period & Frequency	Comments
24	MADD Memorial	Kakaʻako Waterfront Park	Modern / present	Multiple services, random visits; in project area
25	Nagasaki Peace Bell (MLK Day & Anniversary of bombing Aug. 9th)	F. F. Fasi Civic Grounds (South Beretania parking entrance)	1990-present, Annual, 2 ceremonies	Adjacent to project area
26	Florentino Das Commemorative Plaque	Kewalo Basin Park	2011-present	1955 solo 1 yr voyage from Kewalo to Philippines; in project area
Religious and Spiritual Gathering Places				
27	First Chinese Church of Christ	1054 South King Street	1929 – present	Regular Sunday service, additional religious and cultural activities held on grounds; Historic structure, likely eligible for NRHP; adjacent to project area
28	Kawaiahaʻo Church	Corner of Punchbowl * King Streets	1840s - present	Regular Sunday service, additional religious and cultural activities held on grounds; Historic structure with NRHP status; in project area
29	Ke Alaula Oka Malamalama (The Bright Morning Rays of the Church of Reasonable Service)	910 Cooke Street	1880s – present	Regular Sunday service in Hawaiian language; hymns in Hawaiian; Historic religious organization
30	Makiki Christian Church (Site No. 80-14-9719)	829 Pensacola Street	1904 – present	Regular Sunday service; service in Japanese language; Historic structure, Historic structure with NRHP status; adjacent to project area
Public Art Installation & Entertainment Centers				
31	POW! WOW!	Between Queen Street and Ala Moana Boulevard	2010 - present	Various locations of murals featuring local and international artists; week long annual festival
32	Neal S. Blaisdell Concert & Exhibition Complex	Bound by S. King Street, Ward Avenue, & Kapiolani Boulevard	1964-present, used intermittentl y	Three major venues; multiple points of interest; in project area

34	Vacant Lots & Thoroughfares	Various locations in Kakaʻako	Modern / present	Events include: Art & Flea; Eat the Street; Honolulu Night Market; Honolulu 5K and 1 Mile Keiki Run/Walk; King Kamehameha Floral Parade; Pow!Wow! Hawaiʻi; Three Walls Music Festival

5.1 HISTORIC PLACES & LANDMARKS

The Kakaʻako TOD Overlay project area has numerous significant Historical properties. The project is adjacent to Honolulu proper as well as Waikīkī, which have been the backdrop of political and social events that shaped Hawaiʻiʻs complex history. A total of 31 Historic structures in the project area are already registered on the National Register of Historic Places (NRHP) and Hawaiʻi State Register of Historic Places (Figure 19).

A number of Historic places and landmarks still in existence in Kakaʻako have been identified in previous CIA (Wilson Okamoto and Associates, Inc. 2002; Spearing et al. 2008; Vogeler et al. 2010; Genz & Hammatt 2010; Elison and McElroy 2011), including the Kawaiahaʻo Church and Grounds, Mission Houses, Old Kakaʻako Fire Station, Kakaʻako Pumping Station, Mother Waldron Neighborhood Park, McKinley High School, Makiki Christian Church, Yee/Kobayashi Store, and the Royal Brewery Building. However, the HECO Downtown Plant and Mabel Smyth Memorial Building, which are situated within in the project boundaries have not been identified in previous CIA. Furthermore, the Aloha Tower, *Falls of Clyde*, Kapuāiwa Building, Hawaiʻi State Library, Honolulu Hale and Annex, State (Territorial) Office, U.S. Post Office, Customhouse, and Courthouse Building, Dillingham Transportation Building, and U.S. Immigration Office, which are located adjacent to the project had not been previously identified as cultural resources either. While the Kawaiahaʻo Church and Grounds, Mission Houses, and Mother Waldron Neighborhood Park park have been included in previous CIA as Historic Places, this Supplemental CIA identifies them as also being culturally significant in a contemporary sense, where these properties provide a unique space for contemporary cultural practices to occur.

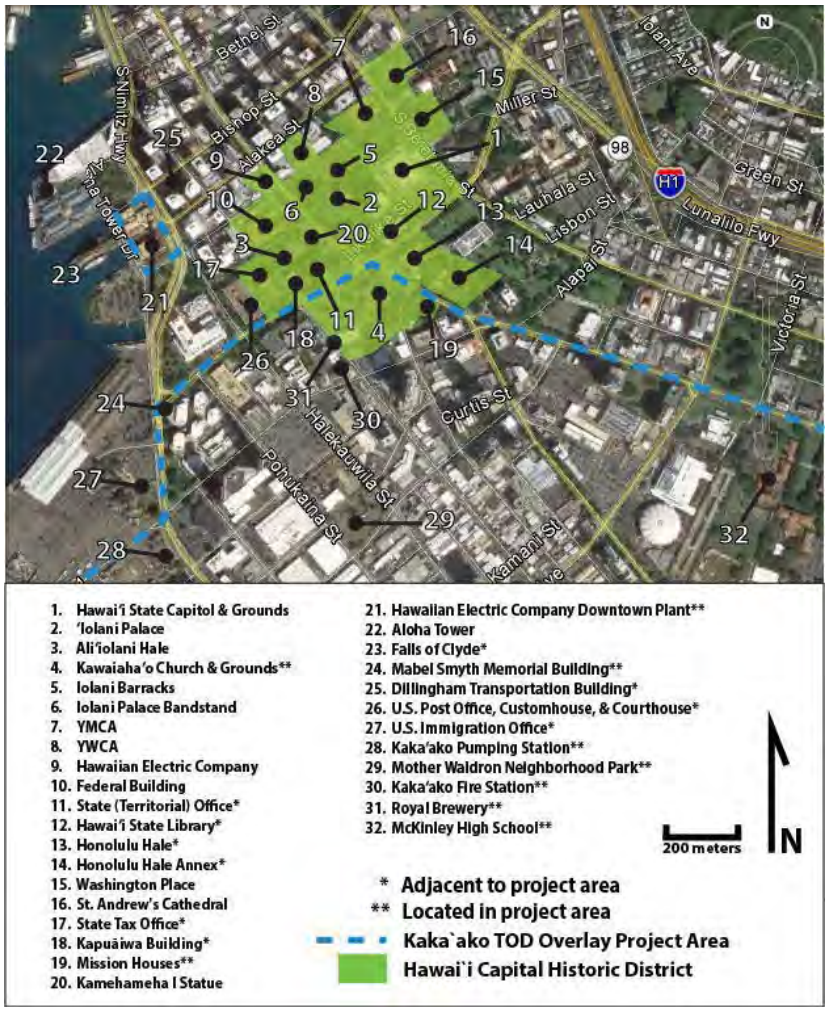

Figure 19. Historic Places & Landmarks located in and adjacent to project area (adapted from Google Earth).

5.1.1 Hawai'i Capitol Historic District

The Hawai'i Capitol Historic District is special district in Honolulu that includes 20 individual Historic Properties (NRHP Reference No. 78001020; State Site No. 80-14-1321). The great majority of the district lies west of the Kaka'ako TOD Overlay project area, but overlaps the project area's northwest corner (Figure 19). The NRHP Nomination Form for the Hawaii Capitol Historic District, which describes the district and most buildings included within, is provided in Appendix E. The Hawai'i Capital Historic District is described in the in the NRHP Nomination Form to have the following characteristics that make it eligible for preservation:

> 1) Open space to building mass relationship: the district encompasses a 57 acre area of which 84% is open space; a building mass to open space ration of 1 to 6.25.
> 2) Visual Access: The district because of its high ratio of open space to building mass, offers a 360°, 57 acre visual plane within a dense urban setting of high and medium high rise structures.
> 3) Architectural Character: The Capital Historic District offers the most cohesive and concentrated historic building categories in the state of Hawaii. These categories include:
> a. Classical Revival
> b. Romansque
> c. Spanish Mission
> d. Italian Mediterranean
> e. French Romanesque
> f. New England Frame (Colonial Rustic)
> g. French Baroque
> h. Georgian (Early Republic USA)
> (NRHP 1978a:2)

Two Historic properties belonging to the Hawai'i Capital Historic District are located in the project area, including the Kawaiaha'o Church and Hawaiian Mission Houses. Both properties have Historic and contemporary cultural significance. A total of 5 Hawaii Capital Historic District properties are adjacent to the project area, including the Kapuāiwa Building, Hawai'i State Library, Honolulu Hale, Honolulu Hale Annex, and State (Territorial) Office.

Kawaiaha'o Church & Grounds

Kawaiaha'o Church is one of the most iconic Historic properties in Kaka'ako as well as a well venerated Christian institution for the island of O'ahu. The church is located in the northwest corner of the project area and is a component of the Hawai'i Capitol Historic District. This "stone" church was constructed mostly of great coral slabs in the early 1840s and has been restored a number of times due to termite damage. A copy of the NRHP Nomination Form for Kawaiaha'o Church, which includes the Mission Houses, is provided in Appendix E for a thorough description and background of the Historic church complex.

Since its erection, Kawaiaha'o Church has been the center of cultural activities for the entire island community. According to the NRHP Nomination Form:

> The historical significance of Kawaiahao Church is indicated by the fact that it is often called "the Westminister Abbey [sic] of Hawaii," Outgrowth of the original Mission Church founded in Boston in 1819 and of the first foreign church on Oahu, it symbolizes the work of the Protestant missionaries, "one of the motivating faces in the life of Honolulu and the Islands." As the state church, it was the scene of many celebrated events--inaugurations, funerals, weddings, thanksgiving ceremonies associated with the Hawaiian kingdom (NRHP 1978b:8).

To this day Kawaiahaʻo Church is the choice setting of important events and ceremonies. The Church and its grounds have been recognized in previous CIA as culturally significant in the past. However, it is important to note that Kawaiahaʻo Church remains to be a major cultural hub for Christians as a cultural group and for the general community of Kakaʻako. The church hosts regular and special events that are open to the community, such as craft fairs, physical fitness classes, youth programs, and Christian based education programs. Site inspections of Kawaiahaʻo Church on the 2nd and 22nd of August verified the contemporary cultural usage of the church and its grounds.

Hawaiian Mission Houses Historic Site and Archives (HMH)

The Mission Houses, located at 553 South King Street, are on the State Register of Historic Places (No.80-14-9991; DUPE State Site No. 80-14-1321) and designated a National Historic Landmark along with Kawaiahaʻo Church since 1965 (Reference No. 66000294) (Appendix E). This Historic complex is also currently a unique cultural learning facility. HMH's Mission Statement is as follows:

> Hawaiian Mission Houses Historic Site and Archives preserves the heritage and interprets the stories of the American Protestant Missionaries, their descendants, and their relationships with the people and cultures of Hawaiʻi, connecting with contemporary life, and encouraging a deeper understanding and appreciation for the complex history that continues to shape Hawaiʻi (HMH website 2013).

Aside from providing access to a large archive of Historic documents and artifacts related to Hawaiʻi's first missions, the HMH hosts free events and offers educational opportunities for the general public to understand the role that missionaries played in Hawaiʻi's History. Public programs consist of "…tours, lectures, family days, workshops, backpacks, teas, exhibitions, and special events" (HMH 2013: Public Programs). Further, HMH offers school programs and events such as a holiday craft fair and public access to an unobstructed view of the Honolulu City Lights Parade, which has been a Honolulu Christmas tradition since 1985. Site inspections of HMH on the 2nd and 22nd of August verified the contemporary cultural usage of the HMH buildings and grounds.

Kapuāiwa Building

The Kapuāiwa Building was constructed in 1884 by George Lucas. The building's location is directly across Punchbowl Street from the project area's western boundary. This two-story, concrete block structure uses an "English inspired ideal of Italian Renaissance" revival style of architecture. The building was originally constructed as a fireproof structure for storing official

government documents, but eventually became a government office building. Although it is a component structure of the Hawaiʻi Capitol Historic District, the Kapuāiwa Building has its own NRHP Nomination Form (NRHP 1973), which is provided in Appendix E. Site inspections of the Kapuāiwa Building on the 2nd and 22nd of August verified the absence of contemporary cultural usage of the building or its grounds.

Hawaiʻi State Library

The Hawaii State Library at 478 South King Street was constructed between 1911 and 1913. The building was designed for the Territory of Hawaii by Henry D. Whitfield in association with Honolulu architect H. L. Kerr and was partially funded by Andrew Carnegie. The library was also supported by Hawaiʻi's royal family and traces its roots to the Honolulu Library and Reading Room Association, which were founded in 1879. This Historic structure is situated on Punchbowl Street directly across from Honolulu Hale and adjacent to the project area's northwest corner. The NRHP Nomination Form (Appendix E) states that the building is significant for the following characteristics:

> 1. The location and scale of the structure is a supplemental element to the total sense/character of the Capitol District. The Hawaii State Library occupies a pivotal position within the architectural landscape of the Capitol District; in conjunction with the Iolani Palace, this building stands at the center of the Capitol District and creates an architectural scale counterpoint to the buildings surrounding the Iolani Palace grounds.
>
> 2. Of particular architectural note is the use of bronze grille work insets in the arches of the main entry, this is the only example of this particular architectural treatment in the State of Hawaii. Also of note is the architect's strict adherance [sic] to classical design principles (except for the inclusion of the Roman derivative arched portico element with bronze grille work) (NRHP 1978a:17).

The building is actively used by the Hawaiʻi State Public Library System as the main library and primary resource center that currently holds more than a half million cataloged books and more than a million items considered supporting materials (HSPLS 2013). The Hawaii State Library hosts numerous exhibits and events a year as well as public installations of art from various genres. The Hawaii State Library is an important contemporary cultural resource utilized by people from all over the island as well as Kakaʻako. Site inspections of Hawaiʻi State Library on the 2nd and 22nd of August 2013 verified the contemporary cultural usage of the library and its grounds.

Honolulu Hale

Honolulu Hale is a late-1920s four-story, reinforced concrete and structural steel, Spanish Colonial/Italian style building with a single six story tower that was designed by architects C. W. Dickey, Hart Wood, Robert G. Miller, Guy Rothwell, and Marcus C. Lester. The building was opened for city use November 26, 1929. Honolulu Hale is located on the corner of King and Punchbowl Streets, directly across King Street from Kawaiahaʻo Church and the project area. A full description is available in the Hawaiʻi Capital Historic District NRHP Nomination Form in Appendix E.

Honolulu Hale was built for the city government, which outgrew the building long ago. The building is now used as the City Hall of Honolulu as well as the Mayor's and City Council's offices. Currently the Mayor's Office of Culture & the Arts (MOCA) currently hosts cultural exhibits that are free and open to the public at the Honolulu Hale Courtyard (MOCA 2013). Although no cultural practices were observed during a site inspection of Honolulu Hale on 22 August 2013, the presence of contemporary cultural usage of the HMH buildings and grounds was found through documentary research.

Honolulu Hale Annex (Mission Memorial Building Complex)

The Honolulu Hale Annex was originally the Mission Memorial Building Complex, which is a two-story high Georgian Revival or Neo-Classical style building on King Street between Honolulu Hale and adjacent to the north border of the project area. In 1915-1916 the Hawaii Evangelical Association commissioned the building of the Mission Memorial Building to commemorate the centennial anniversary of the first missionaries arrival to Hawai'i. The annex, designed by architect Mark Potter, was completed January 12, 1930 and dedicated April 11, 1930. Detail of the structures are provided in the Hawai'i Capital Historic District NRHP Nomination Form in Appendix E. This complex has been home to the Hawaii Evangelical Association headquarters, Kawaiaha'o Seminary, Hawaiian Mission Children's Society, Honolulu Mission Printing Office, and various C & C of Honolulu agencies. The auditorium portion has been restored from office space to a venue where various cultural events are sanctioned (MOCA 2013). According to MOCA (2013), meetings by various City Departments take place during the day and during the evenings and weekends, cultural performances are presented by community organizations at the Mission Memorial Auditorium (MOCA 2013). Although no cultural practices were observed during a site inspection of Honolulu Hale on 22 August 2013, the presence of contemporary cultural usage of the HMH buildings and grounds found through documentary research was not challenged.

State (Territorial) Office Building

The six-story high, reinforced concrete and structural steel Territorial State Office Building was designed for the U.S. Federal Government by architect Arthur Reynolds in 1926 for the Hawai'i Territorial Administrative offices. The Territorial State Office Building is located at the corner of King and Punchbowl Streets directly across from the Hawaii State Library. This Historic property is adjacent to the project area's west boundary. According to the NRHP Nomination Form, the Territorial State Office Building is significant due to its "…location within the Capitol District area; the building and its grounds blend, and add to the total texture, scale, and historic character of the Capitol District" (NRHP 1978a:15). Documentary research found no cultural practices were found to be associated with the structure. A site inspection performed on 10 August 2013 by Kimberly M. Mooney of Pacific Legacy, Inc. failed to identify any current cultural usage of the building or grounds.

5.1.2 Hawaiian Electric Company (HECO) Downtown Plant

The HECO Downtown Plant, located at 222 Ala Moana Boulevard, is not yet recognized by the State of Hawai'i as a Historic site. The power plant, built in 1929, is situated on a 3.4 acre property, which is bound by Nimitz Highway, Bishop Street, Richard Street, and Aloha Tower Drive, is located within the project area. The building is likely eligible as a Historic property, yet it has not been included in any previous CIA as a cultural resource. No cultural practices

have been identified as occurring in or around this property through documentary research and the site survey performed 10 August 2013 by Kimberly M. Mooney of Pacific Legacy, Inc. failed to identify any current cultural usage of the building or grounds.

5.1.3 Aloha Tower

Built in 1926, the Aloha Tower is a iconic 184- foot tall tower is situated Pier 9 of Honolulu Harbor is bound to the north, south, and west by Honolulu Harbor and bound to the east by Irwin Park (Figure 20). This Historic building is located about a tenth of a mile (ca. 150 meters) northwest of to the HECO Downtown Plant portion of the Kaka'ako TOD Overlay project area. Aloha Tower was added to the State Register of Historic Places in 1981 and NRHP in 1976 (State Site No. 80-14-9929 and NRHP Reference No. 76000660), meeting NRHP criteria A and C. A copy of the NRHP Inventory Nomination Form is provided in Appendix E, which describes the history, architecture, and its cultural significance. Smith and Rosendahl (1990) prepared a historical assessment of the Aloha Tower that provides added archival documentary research for the historic property. While the site is recognized as a cultural resource, no CIA to date has included the Aloha Tower as a cultural resource.

Figure 20. Aloha Tower and Aloha Tower Market Place (view to north).

A site inspection was performed on 10 August 2013 by Kimberly M. Mooney of Pacific Legacy, Inc. to determine the extent of cultural usage of the property. The surrounding property was found to continue to function as a commercial marketplace despite the fact that the marketplace is slated to become a residence hall for Hawai'i Pacific University. As a result, many of the commercial spaces appeared to be unoccupied and the grounds fairly void of activity. Therefore, a survey of cultural practices currently occurring in or around the Aloha Tower was inconclusive.

5.1.4 The *Falls of Clyde*

The *Falls of Clyde* is a four-masted, iron hulled ship built in 1878 that is currently moored at Pier 7 in Honolulu Harbor, which is directly across the street from the HECO Downtown Plant portion of the Kaka'ako TOD Overlay project area (Figure 21). This Historic Maritime Landmark was added to the NRHP list in 1973 (Reference No. 73000659) and is also on the SRHP list (Site No. 80-14-9700). Appendix F provides the National Historic Landmark Study for the *Falls of Clyde* (Delgado 1988). According to Delgado (1988:1), the *Falls of Clyde* was "…rescued from destruction, moved to Honolulu and first restored and opened to the public in 1968. Since then, the vessel has undergone continual restoration… and then restored in 1970 to her original ship rig." The *Falls of Clyde*, formerly under the management of the Bishop Museum, is now managed by The Friends of Falls of Clyde (FoFOC), which is a non-profit 501(c)3 organization whose mission is to preserve and restore the ship. FoFOC is currently in the preparation phase for restoring the *Falls of Clyde* and provides monthly updates on their website (FoFOC 2013). A site inspection performed on 10 August 2013 by Kimberly M. Mooney of Pacific Legacy, Inc. failed to identify any current cultural usage of the ship.

Figure 21. The *Falls of Clyde* in repair (view to south).

5.1.5 Mabel Smyth Memorial Building

The Mabel Smyth Memorial Building is located at the corner of Punchbowl Street and Ala Moana Boulevard, which is on the northwest border of the Kaka'ako TOD Overlay project area (Figure 19). This building, constructed in 1941, is listed in the State and National Register of Historic Places (Reference No. 93001558; State Site No. 80-14-9765) due to its Modern Movement/Art Deco/Hawaiian Style architecture and its association with the evolution of modern health care in Hawai'i. According to the NRHP Nomination Form,

> The Mabel Smyth Memorial Building is significant as an example of the work of architect C.W. Dickey and for its associations with the medical profession in Hawaii. In 1937, in reaction to the sudden and early death of Mabel Leilani Smyth, who had for eight years been Superintendent of the Public Nursing Service, there was a Territorial-wide drive to commemorate her accomplishments. A unique center was envisioned, one that would be headquarters for the entire medical profession, in which nurses' and doctors' associations could convene their meetings; a research library could be housed; and where people could gather for educational programs and social interactions (NRHP 1993:8).

Currently the building is home to the Queens Conference Center, which is a venue for medical education, conferences, and meetings within the health care professional community. The complete NRHP Nomination Form is available in Appendix E. Documentary research found no cultural practices were found to be associated with the structure. A site inspection performed on 10 August 2013 by Kimberly M. Mooney of Pacific Legacy, Inc. failed to identify any current cultural usage of the building or grounds.

5.1.6 U.S. Post Office, Customhouse, and Courthouse Building

The U.S. Post Office, Customhouse, and Courthouse Building, also referred to as the King David Kalākaua Building, is located at 335 Merchant Street, which is directly across Punchbowl Street from the project area's western boundary. The structure is three-stories high with two six-story towers built in the Spanish Colonial Revival style in 1922, but expanded in 1929. The Historic structure is registered in the State and National Register of Historic Places (Reference No. 75000620; State Site No. 80-14-9952; DUPE State Site No. 80-14-1321) for its historical significance and architectural style (NRHP 1974). The NRHP Nomination Form is provided in Appendix E for further details. The building was once the official seat of administration in the Territory of Hawaii and state of Hawaii for the United States federal government, but now is solely owned and operated by the State. Documentary research found no cultural practices were found to be associated with the structure. A site inspection performed on 10 August 2013 by Kimberly M. Mooney of Pacific Legacy, Inc. failed to identify any current cultural usage of the building or grounds.

5.1.7 Dillingham Transportation Building

The Dillingham Transportation Building, built in 1929, is a four-story Italian Renaissance/ Mediterranean revival concrete and concrete block structure with three connected wings. It is located at the *makai* end of Bishop Street, across Ala Moana Boulevard of the HECO Downtown Power Plant portion of the project area. The Historic structure is listed on the State and

National Register of Historic Places (Reference No. 79000756; State Site No. 80-14-9900) for its associations with Benjamin Franklin Dillingham, the founder of Dillingham Corporation – a major player in Hawaiian History (NRHP 1973a). The NRHP Nomination Form is provided in Appendix E for a full description. Documentary research found no cultural practices were found to be associated with the structure. A site inspection performed on 10 August 2013 by Kimberly M. Mooney of Pacific Legacy, Inc. failed to identify any current cultural usage of the building or grounds.

5.1.8 U.S. Immigration Office
The U. S. Immigration Office is a complex consisting of five buildings, including the administration building, detention building, lounging shed, garage, and waiting shed. The complex is located on 595 Ala Moana Boulevard, which is adjacent to the southwest boundary of the project area. This complex, constructed in the mid-1930s, is registered in the State and National Register of Historic Places (Reference No. 73000664; State Site No. 80-14-9964) due to its qualities as being a fine example of Hawaiian architect, C. W. Dickey's, work and his ability to adapt architecture to the climate and atmosphere of Hawai'i (NRHP 1973b). The complete NRHP Nomination Form is available in Appendix E. Documentary research found no cultural practices were found to be associated with the structure. A site inspection performed on 10 August 2013 by Kimberly M. Mooney of Pacific Legacy, Inc. failed to identify any current cultural usage of the building or grounds.

5.2 CULTURAL LEARNING FACILITIES

A total of seven cultural learning facilities were identified in the Kaka'ako TOD Overlay project area. These cultural resources provide the entire community of O'ahu as well as the community of Kaka'ako with unique access to cultural knowledge and archives, access to raw and constructed cultural materials, space to create cultural materials, space to enact and perpetuate cultural practices, and space to collaborate with fellow practitioners.

5.2.1 African American Diversity Cultural Center of Hawai'i (AADCCH)
The African American Diversity Cultural Center of Hawai'i (AADCCH) is located in Kaka'ako, and serves as the only repository of documentation and artifacts relating to African American history in Hawai'i. The center has been in existence for 15 years. AADCCH hopes to secure a permanent location in Kaka'ako with increased public access and space for exhibits.

Community Consultation: Ms. Deloris Guttman - AADCCH
Deloris Guttman, Historian and President of AADCCH as well as author of the book, titled *Images of African Americans in Hawai'i*. Guttman was interviewed by Kimberly M. Mooney of Pacific Legacy, Inc. at AADCCH offices on 22 August 2013. She has lived and worked in Hawai'i since 1973.

According to Ms. Guttman, people of African ancestry have played a longer and more pivotal role in Hawaiian history than generally believed. She has been researching and compiling historical documents and artifacts with the assistance of other researchers for decades. Countless tantalizing scholarly dissertation and theses on the subject of African Americans in

Hawaiian Island history can be written based upon tangential story lines that Guttman has come across while performing archival research. She maintains that these untold stories are just waiting to be shared and much of the data is available in AADCCH collections.

The general public has little knowledge of African Americans and people of African descent in Hawaiian history. African Americans played crucial roles in adapting the Hawaiian kingdom to Western style infrastructure, domestic and international diplomacy, education, as well as the arts. Unbeknownst to many, people of African descent first ventured to Hawai'i in the late 1700s as merchant seamen. The most influential of these was Anthony D. Allen of Schenectady, New York. Allen visited many ports around the world before making Honolulu his home in the early 1800s, which was his second voyage to the islands. Shortly after his arrival, Allen became an advisor to King Kamehameha I. He was also a successful entrepreneur and businessman, who built the first hotel, restaurant, bar, and bowling alley in Waikīkī as well as its first hospital on lands located on the site of Washington Middle School, which was given to him by the High Priestess Hewahewa. Among Allen's multi-entrepreurial business ventures included animal husbandry and agriculture. According to Guttman, he supplied his customers with dairy products, meats, and produce. King Kamehameha I himself was among his many patrons. Allen was also involved with the (early infrastructure) building of a permanent roadway in Manoa, now known as Punahou Street.

Allen eventually married a Hawaiian woman and had three children. This was the case with many other men who settled in Hawai'i from abroad. His progeny married and procreated in the islands – some of whom are just finding out about his or her African American ancestry and interested in finding out more about Allen. In AADCCH's collection, the public can find more information about Allen as well as many other persons of African descent who played key roles in Hawaiian history.

MS. Guttman believes Kaka'ako is the cultural "Mecca" of the island of O'ahu, which is why she feels that it is the best location for the AADCCH. Her goal is to open up a cultural learning center that researchers can access and add to the African Americans Hawaiian history data collection as well as provide a space for the general public to view exhibits on the subject. In her opinion, this facility would benefit from the proposed project in terms of increased exposure that the Kaka'ako TOD's added residential and commercial space would bring.

5.2.2 Diverse ART Center
Diverse ART Center is a non-profit youth empowerment resource in Kaka'ako that facilitates classes, workshops and events in music, art, dance and education. The Diverse ART program is designed to develop and build self esteem, self confidence and self awareness in O'ahu's inner-city youth, giving them the opportunity to become respectful contributors to their community, families, and schools. The program allows people to be creative in a positive, supportive and productive environment that brings together a large network of artists from various arts genres. Artists participating in the program work together in teaching classes, holding workshops, producing live events and theater productions, and assist in film making.

Community Consultation: Ms. Nicole Kealoha - Diverse ART Center
Executive Director and founder of Diverse ART Center, Nicole Kealoha, contributed

information regarding the center and program via emails and an online questionnaire between July and August of 2013.

According to Ms. Kealoha, the program has the ability to lower instances of vandalism, violence, and drug abuse as well as increase the number of high school graduates, youths' respect for community and its members, and contributions to the local community (Kealoha 2013). The Diverse ART Center's mission as stated on its website is as follows:

> Diverse Art Center exists to provide creative outlets and opportunities for youth through arts, wellness, and sustainability programming; connecting them with professional performers/teachers who will inspire and nurture the development of self expression with an emphasis on character. Sending them back into their communities as productive contributors (Diverse ART 2013).

The Diverse ART Center is located within the project area at 604 Ala Moana Boulevard and is open to the public Monday through Saturday 4pm-9pm. Ms. Kealoha adds that Diverse ART services "…between 60-70 people a week from all races, demographic[s] and ranging from ages 3-40 yrs" (Kealoha 2013). Classes for various dance styles, such as House, Breaking, Choreo/Street, and Tahitian are regularly held as well as Urban visual arts and music classes. Thus, the Diverse ART Center is another significant resource for the Urban arts community.

Regarding the proposed Kaka'ako TOD Overlay, Ms. Kealoha feels that it is "…another Salt Lake in the making…" where the area is "…being approved piecemeal (project by project)…" (Kealoha 2013). For instance, Ms. Kealoha maintains that the Diverse ART Center had a secure location that is no longer available. She also wonders if Park Dedication fees have been forgotten, as the community of Kaka'ako needs open space for "quality of life" (Kealoha 2013). Further, she states that, "Under the guise of work force housing developers are reaping huge profits. There is no restriction to curb speculator[s]…" (Kealoha 2013).

5.2.3 Hawai'i Children's Discovery Center

Located at 111 Ohe Street in Kaka'ako Makai, The Hawai'i Children's Discovery Center is a unique cultural learning facility for the community of Kaka'ako and island of O'ahu. This facility offers an interactive but safe environment for children to learn about themselves, the natural world, and the many cultures of Hawai'i. This facility is open to the public with a general admission fee, but offers educational programs that works with public and private school children participate in "focused school visits" as well as discounts and membership rates (Hawaii Children's Discovery Center 2013).

5.2.4 Hawai'i Maritime Center

The Hawaii Maritime Center, located at Pier 7 in Honolulu Harbor, was a public maritime themed museum under the management of Bishop Museum, in operation from 1988 to 2009 (Figure 22). According to a Bishop Museum representative, the museum is "currently non-operational and Bishop Museum has no plans to bring the building into operations within the reasonably foreseeable future" (Dettweiler 2013). This museum once celebrated Hawai'i's rich maritime history through exhibits, displays, and rare maritime artifacts. Currently, no cultural practices are identified as occurring in or around the Hawai`i Maritime Center.

Figure 22. Hawai'i Maritime Center, currently closed (view to south).

5.2.5 Nā Mea/Native Books Hawai'i

Nā Mea/Native Books Hawai'i doubles as a Hawaiiana and Pacific retail outlet as well as a cultural learning facility (Figures 23 and 24).

Community Consultation: Mr. Mathias Maas - Nā Mea/Native Books Hawai'i

On 27 August 2013, Mathias Maas, Store Manager for Nā Mea/Native Books Hawai'i, was interviewed by Kimberly M. Mooney of Pacific Legacy, Inc. on the cultural learning center/store grounds.

Nā Mea/Native Books Hawai'i, which has been around for nearly 25 years, is much more than a Hawaiiana and Pacific retail outlet, according to Mr. Maas, it is a vital cultural resource where people can learn about and participate in an array of Traditional Hawaiian cultural practices. The store is one of the few locations that carries almost exclusively *nā mea Hawai'i*, or things having to do with Hawai'i, such as a wide variety of Traditional and contemporary arts and crafts made locally with predominantly local materials, which greatly supports practitioners of Native Hawaiian arts and crafts financially. Mr. Maas explained that because Nā Mea/Native Books Hawai'i specializes in selling these authentic Hawaiian products, the store attracts the type of customer who is willing to pay extra for their merchandize, which allows the practitioner to make a better profit. Ultimately, this affords the practitioner a livable income from his or her product, which helps to preserve and perpetuate these cultural practices by allowing the practitioner to perfect his or her skills, create more traditional products with more authentic local materials, and perhaps have the time to teach others.

Figure 23. One of Nā Mea/Native Books Hawai'i's retail displays (view to east).

Figure 24. A craft production station at Nā Mea/Native Books Hawai'i (view to south).

While Nā Mea/Native Books Hawai'i is primarily a retailer of Hawaiian and Pacific products, it has a doubles as a Hawaiian cultural learning center that serves the general public. Maas holds that people from all over O'ahu, neighbor islands, as well as a great number of tourists visit the cultural learning center/store to purchase hard-to-find Hawaiian products and books as well as

participate in the many classes and activities. According to Mr. Mass, the average age of the Nā Mea/Native Books Hawai'i customer or learner is well into the 30s-40s; yet, the center offers Hawaiian products, classes, and activities for all ages.

An array of Hawaiian centered classes and activities are regularly held at Nā Mea/Native Books Hawai'i. While classes are free, materials are not provided. Visitors can also learn from and or simply enjoy local musicians as they play Hawaiian music or *kūpuna* share *mo'olelo* (storytelling), which play for free regularly– though tips are accepted. Every day the cultural learning center offers at least one activity or class in Traditional cultural practices including a variety of arts and crafts using a range of Traditional methods and materials as well as *lomi lomi* (massage) healing, *hula* (dance), *'ōlelo Hawai'i* (Hawaiian language), and *'ukulele* – to name a few. The cultural learning center arm also works in conjunction with other local cultural organizations to provide specialized workshops for the public. Mr. Maas provided an example, where recently Nā Mea/Native Books Hawai'i held a workshop with Kumu Kahua Theatre to help local writers learn about playwriting. Another example is the multifaceted annual Pow!Wow! Kaka'ako arts event, in which Nā Mea/Native Books Hawai'i helped to organize for the last few years. The center also hosts conferences for professionals in various Hawaiiana based fields, such as writing and publishing.

Additionally, Mr. Maas stated that Nā Mea/Native Books Hawai'i has the most comprehensive selection of new and used Hawaiiana books, including rare or out-of-print manuscripts and those written by local authors that are not available in major book stores. The selection of books at Nā Mea/Native Books Hawai'i focuses entirely on *nā mea* Hawai'i and the Pacific, ranging from Hawaiian history reference books to contemporary books for *keiki* as well a wide variety of CDs and DVDS. The book selling arm of the store, though commercial in nature, also functions to preserve and perpetuate Native Hawaiian traditions. For those who may not have direct access to *kahu* of a specialized practice or *kūpuna* for oral traditions, books can be an invaluable cultural resource. In some cases, Nā Mea/Native Books Hawai'i provides access to out-of-print reference books to Native Hawaiians researching their genealogy.

In regards to the proposed development, Mass maintains that Nā Mea/Native Books Hawai'i is supportive of the proposed Kaka'ako TOD Overlay project. Mr. Maas believes that the proposed development will revitalize Kaka'ako and provide a sound architectural landscape that will bring in families and likely increase patronage at Nā Mea/Native Books Hawai'i. Further, he holds that it's better to keep major development within the footprint of previously disturbed lands, such as Kaka'ako, rather than developing undisturbed or agricultural lands which often occurs with "urban sprawl."

5.2.6 The Refuge (808 Urban)

808 Urban is a 501 (c) (3) grassroots Non-Profit Organization (NPO) self described as "a collective of community cultural workers: artists, organizers and volunteers committed to improving the quality of life for our communities through arts programming," according to the 808 Urban website, that mentors youths in creative and entrepreneurial aspects of urban arts. In short, the intent of 808 Urban is to prepare young artists for real world situations. The Refuge, 808 Urban's Kaka'ako based workshop currently located at 683 Auahi Street, provides a safe space for youths to collaborate with professional artists and peers while developing artistic

skills (Figure 25). It gives them a real world understanding of art as a trade and how to make a living as an artist or arts professional. The Refuge is also a site for creating introspective and expressive art as well as selling the art produced by 808 Urban mentees.

Community Consultation: Mr. John "Prime" Hina and Ms. Sierra Dew – 808 Urban

Founder of 808 Urban, John "Prime" Hina, and Co-Director and Program Manager of The Refuge, Sierra Dew, were interviewed together on 2 August 2013 by Kimberly Mooney of Pacific Legacy on site at The Refuge.

Mr. Hina began his art career in Hawai'i as a graffiti artist in the 1980s, before it was culturally accepted and typically illegal or associated with an array of illegal activities. Having experienced the dangerous lifestyle of an at-risk youth, Prime has a unique understanding of these kids' lives and the importance that artistic expression holds for them. With tough love and a passion for art, Prime keeps these aspiring artists on track and focused. He also understands the need for youths to be mindful of Hawaiian history and culture by incorporating traditional Hawaiian values into the art program and sharing traditional *mo'olelo* and the cultural landscape of the ancient Hawaiians. He also encourages the participants to fully embrace their own ethnic roots (e.g. Filipino, Japanese, Hawaiian, etc.) and to express it in their art. Much of his recent art projects tie in or focuses on his roots, providing a contemporary visual interpretation of traditional Hawaiian values and beliefs.

With a formal education in fashion and textile-arts as well as experience as a youth center volunteer and entrepreneur in the arts trade, Ms. Dew balances the 808 Urban and The Refuge collective. Growing up in the small Maui town of Pā'ia and being practically raised in the family store, Mana Foods, which is the most prominent cultural hub for the health and environmentally conscious in Maui, Sierra was rooted in a social movement that centered on feeding the bodies, souls, and minds of the community. With this background and her own experiences as a professional artist, she quickly saw the need for such a movement on O'ahu and wholeheartedly joined the 808 Urban cause.

Initially, 808 Urban was largely a mobile mentoring program for at-risk youth with the goal of urban arts and cultural education that started in Prime's backyard back in 2006. At that time, society in general did not embrace graffiti as art. Yet, Prime and Sierra recognized that this genre of art goes hand in hand with urban development. Being that the landscape was becoming increasingly urban, they felt that it was important to teach youths, who are largely influenced to destroy or deface buildings and walls; that they can instead work with business owners and developers as co-creators in integrating art into the urban landscape. Sierra and Prime added that the 808 Urban mentorship program was also designed to teach adolescents the importance of preserving and conveying the history of Hawai'i and celebrating its many cultures and ethnic groups through art. 808 Urban's mentorship program was intended to help aspiring young artists in a public school paradigm that devalues art and defunds art programs. After several years of operation, Prime and Sierra found the logistics of youth mentoring without a dedicated facility to be troublesome. In February of 2013, 808 Urban found a space in Kaka'ako to run the program out of and named it The Refuge. Although Chinatown with its vibrant people, sights, sounds, and smells has been the default location for emerging artists and where Prime spent a good portion of his youth, he felt that the adjacent community of Kaka'ako

was the better location for The Refuge. According to Sierra and Prime, the arts community of Chinatown benefits little from such events as First Friday and other street fairs that do more to diminish art and promote debauchery. Further, with Chinatown's relatively high density of bars, prostitutes, and homeless, both felt that it was not suitable as a permanent base for the program. To them, Kaka'ako was the natural choice for The Refuge, with its urban setting, multifaceted and open-minded community, rich background, affordability, centrality, and growing arts culture. Kaka'ako, as a community, has also become increasingly unified with a sense of shared culture and community interest. 808 Urban among other local artists in Kaka'ako have come to accept the impending development of the area; yet, they feel they have a responsibility to ensure that Kaka'ako maintains its cultural identity and honors its people as well as its past throughout the course of its development.

808 Urban and The Refuge have become unique and significant cultural resources for the arts community where aspiring young artists have the opportunity to work with and be mentored by a dynamic and diverse group of professional artists as well as non-artists who work within this community. Program mentors specialize in an array of conventional visual arts, film making, and graphic design as well as organizing events and other activities supporting the arts. The mentorship program, referred to as the Junior Board Initiative, is exceptional in that its mentors are professional artists, rather than educators, who understand how an individual can make a living from art in the real world. Prime holds that the mentorship program does not teach kids how to create art; it teaches them how to live and be successful as a professional artist. The program also allows youths to participate in the organization as board members, where they partake in decision making, fund raising, grant-writing, budgeting, and governance within the non-profit organization. They are given the opportunity to engage in real world, grassroots community organizing and activism, which potentially gives them the skills and courage to change the system or make it work to their advantage.

Mentees have the opportunity to express themselves in a way that does not break laws, but rather, helps them to be community oriented and work in accordance with the law. The program encourages their mentees to work with neighborhoods to help express its unique character through art. To date, 808 Urban's mentees have successfully installed numerous murals from Waipahu to Punahou by working with the respective communities. Sierra and Prime are working to expand the program to other islands.

Another facet of the program allows mentees to engage as entrepreneurs in the arts marketplace to experience first-hand the trial and error processes at an earlier age than most aspiring artists. These youths also have the support of 808 Urban *ohana* while testing the sometimes harsh waters of art entrepreneurship.

According to Sierra, The Refuge is like a "home away from home" and the participants are like family. For many aspiring artists, especially at-risk youths, a space conducive to expressing themselves is rare, so for those who are fortunate to make it into the program, The Refuge is exactly what its name suggests.

In regards to the proposed Kaka'ako TOD development, Prime and Sierra are concerned about the population increase that will follow vertical development putting further strain on

resources, such as water. They feel that the development should incorporate more architectural features that conserve resources, such as water catchment and rooftop gardens. So far, they hold that the proposed structures exhibit minimal measures to conserve resources. Sierra and Prime also worry that lease and utility rates will increase to a degree that 808 Urban and The Refuge would be forced out of the area.

Figure 25. 808 Urban's headquarters, The Refuge (view to the south).

5.2.7 Home of the Brave Tour

The Home of the Brave Tour is a family-owned and operated World War II tour and museum that is a one-of-a-kind repository and interpretive center designed to remember, honor, and salute those who served in World War II (Figures 26 and 27). The museum complex is hidden among Kaka'ako's warehouses and is fast becoming Kaka'ako's best kept secret. The museum provides public tours with admission fee to view literally thousands of World War II artifacts and memorabilia that provide unique insights into WWII and an intimate understanding of the soldiers and their experience. While the U.S. Arizona Memorial and other museums tend to render a visitor to solemnity and tears, the Home of the Brave Tour offers a well-rounded experience where the visitor feels as if they've transcended into a 1940s E-Club and can hear all of the amazing WWII war stories as the veterans themselves would have told them.

Community Consultation: Glen Tomlinson – Home of the Brave Tours

Home of the Brave Tours President, Glen Tomlinson, was interviewed by Kimberly M. Mooney of Pacific Legacy, Inc. at the Home of the Brave Tours museum complex on 27 November 2013 to provide further insights on the cultural significance of the Home of the Brave Tours and museum.

Home of the Brave Tours initially began as a bus tour of Hawai'i's WWII battlefields in December of 1991 to commemorate the 50th Anniversary of the attack on Pearl Harbor. As years passed, the tours grew in size. Due to the popularity of the tour, Mr. Tomlinson decided the tour needed a headquarters with a participant receiving area and gift store. Already in possession of an impressive WWII artifact and memorabilia collection, Tomlinson began showcasing his collection at the tour headquarters. When tour participants, mostly WWII veterans and their families, witnessed Tomlinson's passion for the era as well as his gift of storytelling and interpretive design, they began donating artifacts, personal memorabilia, and intimate stories of their experiences to Home of the Brave Tours museum. Other WWII collectors in the community came forward eventually and lent their collections to the museum to be shared with the public. As the Home of the Brave Tour's museum collections grew through donated and loaned artifacts, Tomlinson expanded the facility year by year into adjacent Historic structures, including a horse stable, incorporating many Historic structural elements into the new design. The museum has grown over the twenty years of its existence from a single room operation to a two-story complex with nearly a dozen rooms and niches filled from floor to ceiling with fascinating photos, replicas, and artifacts from the WWII and 1940s era.

Each room, niche, and display cabinet is themed and Tomlinson guides the viewer from room to room, interpreting the themes and recounting stories with such passion and proficiency that one would think he was a WWII veteran himself. The stories behind each picture or artifact, most of which have been handed down from his veteran tour participants, is worthy of being a Hollywood movie. The museum is also very hands-on, where you can have your photo taken sitting on a WWII era Army issue Harley Davidson motorcycle or a group photo in one of the two vintage army jeeps. With antique televisions and radios softly playing the sights and sounds of the 1940s, one could not help but feel as though they've been transported back in time.

The museum, which Tomlinson likes to call a "Brewseum," even has its own 1940s style *tiki* bar with outdoor lanai where tour participants can enjoy a hand-crafted Home of the Brave beer, root beer, or coke in a glass hobble-skirt bottle. Tomlinson is currently in the process of expanding into a nearby warehouse to house his upcoming banquet room and entertainment venue as well as the brewery for the hand-crafted beers produced by Tomlinson's sons. According to Tomlinson, the Home of the Brave Tour is currently considering an evening tour through the museum.

The Home of the Brave Tour is culturally significant for several reasons: 1) the museum is a repository and interpretive center showcasing thousands of artifacts and replicas that embody WWII; 2) Tomlinson and his trained tour guides have become cultural resources themselves as the custodians of countless WWII oral histories, many of which have not yet been recorded; and 3) we are losing our surviving WWII veterans at a growing rate, as the average WWII veteran is in their 90s. Thus, the Home of the Brave Tours preserves and shares these cultural resources in a way that is matchless. According to Tomlinson, their collections are invaluable because they represent the lives and accomplishments of our country's "Greatest Generation," of whom we are losing at a higher rate year by year.

Figure 26. One of Home of the Brave Tours and museum displays.

Figure 27. Home of the Brave Tours' "Wall of Fame" exhibiting photos of WWII veterans.

Currently, the Home of the Brave Tours and museum complex is firmly rooted in Kaka'ako from the unique Historic structure it is housed that has been painstakingly modified over twenty years to display the collections to its central locality and affordable rent. While parking is hard to come by, the Home of the Brave Tours is primarily accessed by tour buses. Tomlinson is considering expanding the hours of operations to increase visitation at present,

but holds that finding and employing specialized staffing, additional parking, and security of the many priceless artifacts are obstacles. In regards to potential impacts caused by Kaka'ako TOD Overlay project, Tomlinson's only concerns are that the property that houses his museum may be bought out and the museum would have to relocate.

5.3 Public Parks and Grounds

The majority of public parks and grounds are located in Kaka'ako Makai and are under the jurisdiction of HCDA. Kaka'ako Makai, Kewalo Makai Gateway, and Kolowalu Parks are located in the Kaka'ako TOD Overlay project area. Information regarding cultural activities occurring in these parks was largely obtained from published literature and community consultations.

For parks managed by the City and County (C & C) of Honolulu, Department of Parks and Recreation, information regarding all sanctioned activities was obtained from the parks permit registry, which was graciously provided by department officials to aid in this assessment. To add insight to selected cultural practices, community consultations were performed. Parks in and around the Kaka'ako TOD Overlay project area under the jurisdiction of C & C include Mother Waldron Neighborhood Park, Ala Moana Beach Park/McCoy Pavilion, and Thomas Park. According to the C & C, over five hundred thousand people participate in permitted events in Mother Waldron Neighborhood, Ala Moana Beach/McCoy Pavilion, and Thomas Parks (Table 15). Additionally, the annual estimate of casual visitors to these parks is approximately two million for the year 2013. No permit information was available for Irwin, Walker, or Sheridan Parks.

Table 17. City & County of Honolulu Parks 2012-2013 Annual Usage Summary

No. of Permits	Description	No. Of Participants
2,027	Ala Moana Park, Magic Island, Thomas Square: Picnic Permits	161,395
115	Ala Moana Park, Magic Island, Thomas Square: Special Events	272,770
139	Ala Moana Park, Magic Island, Thomas Square: Ongoing Permitted Activities	25,275
342	McCoy Pavilion: Special Events	24,065
10	Mother Waldron Neighborhood Park: Special Events	21,625
72	All Parks: Filming Permits	3,100
12	Ala Moana Park, Magic Island: Commercial Activity (scuba, surf)	1,560
2717	**All permitted activities**	**509,790**

5.3.1 Kaka‘ako Waterfront Park

Situated on the southern terminus of the Kaka‘ako Peninsula, which is located at the end of Keawe, Ahui, and Ohe Streets, is Kaka‘ako Waterfront Park (Figures 28 and 29). This roughly 30-acre park was constructed over a former municipal landfill in 1992. Kaka‘ako Waterfront park offers shore fishing and ocean access for body surfing, swimming, and diving as well as an amphitheater, a waterfront promenade, picnic areas, restrooms, trash cans, water fountains, and an expanse of rolling grass hills with observation areas to view Waikīkī and Diamond Head. Kaka‘ako Waterfront Park also has 300 public parking spaces available. In addition, the park is home to two culturally significant memorials, including the Ehime Maru Memorial and the Mothers Against Drunk Driving (MADD) Victim Memorial. Currently, Kaka‘ako Waterfront Park is under the management of the Hawaii Community Development Authority (HCDA), which issues permits to groups for large events.

Figure 28. Kaka‘ako Waterfront Park promenade and public facilities (view to east).

The park is used daily by local residents, people who work in Kaka‘ako or attend the nearby universities, people living in other communities on O‘ahu, and tourists. Park visitors enjoy a wide variety of marine activities at Kaka‘ako Waterfront Park’s waters including body surfing, body boarding, surfing, swimming, diving, and fishing. Point Panic is held by many as one of O‘ahu’s best body surfing breaks and is sanctioned for body surfing only. Thus, several long-standing body surfing competitions are held at Point Panic several times a year, including:

- HASA Surf Series
- Redwings Memorial World Championship of Handboarding and Paepo Boarding
- Point Panic Bodysurfing Club’s Hawaiian Bodysurfing Championship

Kaka‘ako Waterfront Park is also utilized for an array of public recreational activities that don’t require water, such as walking, jogging, roller skating, bicycle riding, yoga, tai chi, picnicking, sun bathing, and relaxing to name a few. This park offers Kaka‘ako residents and workers a needed escape from the urban landscape of Kaka‘ako. However, occasionally the park hosts larger events that people from all over the island participate in, including:

- Live music concerts held at the amphitheatre (various genres of music)
- The Love Festival (annual)
- Hele On Kaka‘ako! (Kakaako 5k Run & other activities)
- Fireworks viewing (New Year’s Eve and 4th of July)

Figure 29. Kaka‘ako Waterfront Park Amphitheatre (view to north).

<u>Community Consultation: Mr. Wayne Takamine – Kaka‘ako Makai</u>

To offer an insider’s perspective on Kaka‘ako Waterfront Park, Mr. Wayne Takamine, who is a long-time body surfer and surfer of Kaka‘ako’s waters as well as the Chair of Kaka‘ako Makai Community Planning Advisory Council (CPAC) was consulted. Although the Kaka‘ako Makai CPAC collaborates with HCDA and other planning consultants, Mr. Takamine was recommended by Ron Iwami (Friends of Kewalos) and Robert H. Richmond, Ph.D. (Research Professor and Director at Kewalo Marine Laboratory) as one of the most knowledgeable informants on recreational and cultural activities occurring in Kaka‘ako Makai. Mr. Takamine was interviewed as a cultural informant by Kimberly M. Mooney of Pacific Legacy on 25 October 2013 at Kaka‘ako Waterfront Park.

Kaka‘ako Makai’s parks and promenades, including Kaka‘ako Waterfront Park, Kewalo Basin Park, Ala Moana Park, and Kaka‘ako Gateway Park are utilized by a variety of individuals and cultural groups within the community on a daily basis. But, according to Mr. Takamine, water

sports and recreation enthusiasts are the largest cultural group that rely on Kaka'ako Makai. This group generally consists of fishermen, surfers, body boarders, body surfers, paddle boarders, paddlers/kayakers, swimmers, divers, and boaters. These water sports and recreation groups are comprised of individuals of all walks of life and hail from all areas of the island. Most water sports and recreation enthusiasts are driven by the surf and water conditions. Just as most parks do, these waterfront parks have their regular recreation enthusiasts who use the ocean for sport, recreation, and sustenance. When not actively surfing or recreating in the water, many of these people remain for extended times at the various waterfront parks to relax, picnic, and/or enjoy the panoramic shoreline views with fellow waterfront regulars.

People from across the island can be found participating in an array of activities, both organized and random, including jogging picnicking, barbequing, tai chi, cardboard sliding on grass slopes, and relaxing. There are also many music concerts held at the Kaka'ako Waterfront Park Amphitheatre. Newlyweds, mostly Japanese, can be seen taking wedding photos at the waterfront promenade as well. Several major events are attended at Kaka'ako Waterfront Park and other Kaka'ako Makai parks by thousands of people annually, including the 4th of July and New Years' Eve fireworks displays. Mr. Takamine holds that people from all over the island come as early as the night before the event to secure a good spot to view the fireworks.

There are several well-known surf breaks along the coast of Kaka'ako. The most renowned break for the area is Point Panic, located off of the east end of Kaka'ako Waterfront Park. Point Panic is one of the only breaks in town soley reserved for body surfing, which is regularly enforced to keep board surfers from dominating the waves. Mr. Takamine has been participating in the Redwings Memorial competitions at Point Panic for twelve years, but holds that the events have been going on for at least twenty years. He describes the events as large enough to occupy the entire southeast corner of the park and parking lot. The next surf breaks to the west are called "Flies" and "Incinerators." These names were given to the surf break at a time before Kaka'ako Waterfront Park existed and the "land" was actually the landfill refuse, which is now what lies beneath the park. These breaks are accessible to board surfers.

To the west of these breaks is a swimming cove that is protected by a sea wall with stairs leading into the water. Local kids as well as Micronesians can be found swimming and jumping off of the rock walls of the cove. Mr. Takamine holds that the long and deep culvert located west of Kaka'ako Waterfront Park is used for recreation by people who live at The Next Step homeless shelter, despite the fact that the culvert is frequented by large sharks.

Further to the west are popular fishing spots, where people fish by pole and spear both day and night. Fishing occurs all along the waterfront at different times of the day. An array of species are caught in these waters, but Mr. Takamine states that *pāpio*, *puhi*, and *hīnālea* are common catches *and uhu, weke, moana,* as well as *he'e* can also be caught. He also has seen *'a'ama* crabs and small *'opihi* and *hā'uke'uke* on the rock sea wall. In the past he recalls there being regular schools of *āholehole* and *halalū*. He adds that the non-profit Kewalo Keiki Fishing Conservancy, which operates out of the west side of Kewalo Basin, is an important cultural resource for the area's youths.

Kaka'ako Waterfront Park also has several memorials, including the Ehime Maru Memorial, around which annual services are held for the victims of the tragic accidental sinking of the Japanese research vessel by a U.S. Navy Submarine. Another memorial is the Mothers Against Drunk Driving (MADD) Victim Memorial, which is visited by family and friends of victims on random occasions and scheduled memorial events. While these memorials were erected by the HCDA, the practice has been discontinued to ensure unobstructed recreational use of the remaining park open space.

Mr. Takamine's concerns regarding HCDA's management of Kaka'ako Waterfront Park and other coastal parks in Kaka'ako Makai, are as follows:

- maintaining and increasing open park space;
- maintaining open public access to our established ocean recreational areas;
- mitigating problems from adverse overcrowding and over-development impacts on cultural and recreational shoreline park uses;
- addressing ocean water quality concerns from storm water runoffs, as such may adversely impact and endanger shoreline recreation uses; and
- establishing a critical ocean safety and lifeguard facility to ensure effective first-responder and emergency treatment of shoreline park water users

As Chair of CPAC, Mr. Takamine recommends that CPAC's Kaka'ako Makai Vision and Guiding Principles be consulted to fully understand the cultural significance of the area and to responsibly plan development for areas included in Kaka'ako Makai. A copy of the Kaka'ako Makai Vision and Guiding Principles is provided in Appendix H.

5.3.2 Kewalo Basin and Park

While Kewalo Basin Park was thoroughly evaluated in the CIA for the Kewalo Basin Repairs Project (Genz and Hammatt 2010), several events and cultural practices were overlooked. For example, Genz and Hammatt (2010) identified four surf breaks "Marineland," "Straight Outs," "Rennicks/Right Next," and "The Point," off of Kewalo Basin, but it is important to add that these breaks are not only utilized by locals (Figure 30). Several times a year when the surf is high at these surf breaks, scores of water sports enthusiasts from all corners of the island gather to participate in or watch surfing, body boarding, and paepo boarding competitions. The three major competitions held in these waters are:

- HASA Surf Series
- Royal Richard Memorial World Championship of Paepo Boarding
- Redwings Memorial World Championship of Handboarding

Site inspections of Kewalo Basin and Park on the 2nd and 15th of August verified a variety of contemporary cultural activities in the basin as well as the park buildings and grounds.

Figure 30. Point Panic surf break with Diamond Head in background (view to east).

Community Consultation: Mr. Ronald Iwami and Mr. Thomas Iwai, Jr. – Friends of Kewalos

On behalf of Friends of Kewalos, Ronald Iwami and Thomas Iwai, Jr., were interviewed by Kimberly M. Mooney of Pacific Legacy, Inc. at Kewalo Basin Park on 15 August 2013 to provide further insights on the cultural significance of Kewalo Basin and Park. Mr. Iwami is a long-time Kewalos surfer and President as well as founding member of Friends of Kewalos, which started in 2005 as the grassroots organization, Kewalo Basin Park Association. In 2009, the association was renamed Friends of Kewalos and granted 501 (c) (3) Non-Profit Organization (NPO) status. Mr. Iwai is also a long-time Kewalos surfer, fisherman, fisheries and aquaculture consultant, and Board Member of Friends of Kewalos.

The mission statement of Friends of Kewalos is:

> To Protect, Preserve, and Malama Kewalo Basin Park and the surrounding shoreline and ocean, to ensure that the recreational user will continue to have access and the ability to enjoy the area for future generations to come (Friends of Kewalos 2013).

Friends of Kewalos represent and consist primarily of Kewalo Basin Park users, who come from all over Oʻahu to participate in an array of activities such as surfing, fishing, diving, picnicking, exercising, and relaxing – just to name a few activities. Kewalo Basin and its park, which is located within Kakaʻako Makai on the outside of the basin, unites many of its users as a choice location for these cultural activities and has been a "way of life" for those who have frequented the park for much of their lives. According to the Friends of Kewalos brochure, "It is a place where lifelong friendships have evolved and everybody knows your name. The parks' location in the heart of Honolulu, quiet charm, low-key atmosphere, and beautiful vistas of Diamond

Head and the ocean, keep all of us coming back" (Friends of Kewalos 2013). Thus, Kewalo Basin is an important cultural activity area that has developed a distinct culture shared by its regular users. The Friends of Kewalos embodies this culture and works with numerous water sports, business, watchdog, and conservation groups to *mālama* Kewalos and other localities within Kakaʻako Makai. Furthermore, Friends of Kewalos regularly organizes events to unite Kakaʻako's community and other Oʻahu residents for beach cleanups and peaceful rallies centered on keeping the beaches, waters, and parks of Kakaʻako Makai open to the public.

According to Mr. Iwami and Mr. Iwai, the coasts of Kewalo Basin and Kakaʻako Waterfront Parks are renowned for having excellent surf breaks, which are utilized by scores of surfers, body surfers, body boarders, and hand boarders. Surf breaks that line Kakaʻako's coast, such as "Marineland," "Straight Outs," "Rennicks," "Points," and "Point Panic" are locations that many of the above mentioned sports hold annual contests. Other cultural activities include swimming, paddling, and stand-up-paddling. Fishing and aquatic gathering are also common activities at Kakaʻako Makai beaches, where an array of reef and open ocean fish are caught. Also, *tako* or *heʻe* (octopus) is still speared off of Kewalo Basin Park using the glass bottom box methods and snorkeling. Both informants have witnessed several species of *wana* (sea urchin) being collected by Sāmoan and Micronesian families for food as well.

Mr. Iwami has a few key concerns regarding the proposed Kakaʻako TOD Overlay: 1) residential development of Kakaʻako Makai; 2) limited access to the coast for those who do not live in Kakaʻako; and 3) parking for the various beach parks and ocean access points. Keeping Kakaʻako Makai free of condos and timeshares has been a key concern for Mr. Iwami over the years. He advocates for "smart and responsible growth," where developers need to show the public the "big picture" and how the end product, which includes an influx of approximately 30,000 people, will impact infrastructure and traffic in already congested areas. In regards to accessing the coast from areas outside of Kakaʻako, Mr. Iwami is concerned that key thoroughfares used to travel from *mauka* to *makai*, including Ward Avenue, Punchbowl Street, Pensacola Street, and Piʻikoi Street, will be impacted by increased traffic created by the increased population and business. Due to the fact that he does not live in an area serviced by the proposed rail and that he has surfboards to transport, he would not likely use the rail to access Kewalo Basin Park. Therefore, his only option is to drive to and park at Kewalos, which is a situation shared by many other Kewalo Basin Park users. A personal vehicle may be the only feasible way to transport surfboards, diving gear, fishing tackle, or picnic supplies from areas outside of Kakaʻako. Thus, Mr. Iwami holds that free and ample parking spaces as well as open avenues leading to the coast are crucial to Kakaʻako Makai park, beach, and ocean users.

Mr. Iwai, who recently retired from the Hawaiʻi State Division of Aquatic Resources (DAR), has a unique perspective on the impacts of conservation laws on traditional and commercial fishing practices from his many years of employment at DAR. Because Mr. Iwai is himself a fisherman and aquaculture practitioner, he has strong concerns about the marine ecosystem as well as fishing rights. He holds that federal agencies, conservation organizations, and academic institutions that sponsored, created, and implemented wildlife conservation laws often disregarded the effects of these laws on local jobs and cultural practices, such as fishing for sustenance and/or livelihood. He suggests that many of these laws enter the books as temporary conservation measures, but become permanent over time with no further studies to

determine whether or not they are warranted, if the laws benefit the subject species, or even if they harm the marine ecosystem in the long-term. Further, Mr. Iwai maintains that Environmental Protection Agency (EPA) regulations are often based on mainland studies then applied to Hawai'i, which has different environmental variables. Therefore, many regulations are not easily implemented, fail to protect natural resources, and are expensive. While he feels as though the laws have the right outcome in mind, they often have short-term positive outcomes andcause long-term negative effects on local fishing and aquaculture practices. According to Mr. Iwai, traditional fishing practices are already struggling for a variety of reasons. For example, the *Nisei*, which was the last remaining *aku sampan* (Traditional Japanese skipjack tuna boat), out of Kewalo Basin is no longer in operations due to high operational costs. Ultimately, Mr. Iwai's concern is that the proposed Kaka'ako TOD Overlay will incorporate regulations or support legislation based on wildlife conservation studies that are not tailored to the local ecosystem or outdated, especially when the laws impact local marine based jobs and cultural practices.

5.3.3 Kaka'ako Makai Gateway Park

Kaka'ako Makai Gateway Park is 4-acres of open, flat grass field that is bound by Ala Moana Boulevard to the north, Cooke Street to the west, the parking lot for Kaka'ako Waterfront Park to the south, and Ohe Street to the east. This park is also utilized for a variety of recreational and sports activities by Kaka'ako residents and those who work or attend the nearby universities. Park users can be seen playing a variety of field sports, exercising, flying kites, and participating in other forms of recreation on a daily basis. Because of the large, flat expanse, this park is also a good venue for fairs, bazaars, rallies, and other public gatherings. Several events have occurred at Kaka'ako Makai Gateway Park drawing visitors locally and from areas outside of Kaka'ako, such as Kaka'ako Kalikimaka, Aloha Pet Festival, and Film & Food: Pop-up in the Dark. This park is also managed by HCDA, who grant permits for park events. Site inspections of Kaka'ako Makai Gateway Park on the 2nd and 15th of August 2013 verified a variety of contemporary cultural activities occurring at the park.

5.3.4 Mother Waldron Neighborhood Park

Although originally named Mother Waldron Playground, this park is often referred to as Mother Waldron Park and is now officially named Mother Waldron Neighborhood Park. The park, located within the project area, has been on the Hawaii Register of Historic Places since 1988 along with several other parks grouped under of the thematic group "City & County of Honolulu Art Deco Parks" (Site No. 80-14-1388). Mother Waldron Neighborhood Park has been recognized as a cultural resource for its history in previous CIA (Spearing et al. 2008; Elison & McElroy 2011; Elison 2013; Maly et al. 2013), however, no mention of what current cultural activities take place at the park. According to the C & C of Honolulu, Department of Parks and Recreation, in addition to an array of recreational and sports activities carried out by casual-use visitors on a daily basis, five permitted events (single day events and reoccurring) are scheduled for Mother Mother Waldron Neighborhood Park in 2013 (Table 18), totaling in nearly 22,000 participants for the year. Site inspections of Kaka'ako Makai Gateway Park on the 2nd and 22nd of August 2013 verified a variety of contemporary cultural activities occurring at the park.

Table 18. Mother Waldron Neighborhood Park permitted activities and events for 2013

Organization	No. of days	No. of Attendees	Total	Purpose
Hawaii Jokgu Assn.	50	25	1250	Jokgu league
Ke Aloha Ho'okahi Preschool	250	35	8750	P.E. activities
Voyager Charter School	250	45	11250	P.E. classes
Cycle on Hawaii	1	300	300	"Hele On Kaka'ako" event
Olanui Church	1	75	75	Church picnic
Totals	**552**	**105**	**21625**	

5.3.5 Ala Moana Beach Park/McCoy Pavilion

Immediately to the south of the Kaka'ako TOD Overlay project area is Ala Moana Beach Park, which includes the McCoy Pavilion located in Ala Moana Beach Park. This park, constructed in the early 1930s, encompasses approximately 76-acres of waterfront property, which consists of a 4000-foot long by 150-foot wide gentle-sloping sandy beach as well as the McCoy Pavilion, a lawn bowling complex, expansive grass fields, tennis courts, and a few small ponds. The waters of Ala Moana Beach feature a l000-meter long channel parallel to the beach that is protected by a reef. These calm water conditions make Ala Moana Beach Park a hot spot for swimmers, families with young children, and stand-up paddle surfers. The City and County Department of Parks and Recreation provided a list of all registered events occurring within Ala Moana Beach Park to aid with identifying cultural activities. Numerous long-standing cultural practices have been identified as occurring in or partially in Ala Moana Beach Park/McCoy Pavilion, including:

- Lantern Floating Festival
- Dragon Boat Festival
- Boy Scouts of America Makahiki
- Aloha Floral Parade
- Martin Luther King, Jr. Parade
- Greek Festival
- Talk Story Festival
- Pride Festival
- Honolulu Gay Pride Parade
- Lei Queen Selection events
- Hui Wa'a/OHCRA Canoe Paddling Practice & Races
- Interscholastic League of Honolulu (ILH) Canoe Races
- Honolulu Marathon & Triathlon
- Charity Runs & Walks (various causes)
- Baptisms (group and individual)
- Car Shows (various clubs)
- PetWalk (Hawaiian Humane Society)
- U.S. Tennis Association Lessons & Tournaments
- Gateball & Groundgolf

Community Consultation: Mr. Roy Ho - Lantern Floating Hawaii

The annual ceremony of Lantern Floating Hawaii at Ala Moana Park, which is officiated by the Buddhist Order, Shinnyo-en, and presented by Nā Lei Aloha Foundation, is becoming one of Hawai'i's most cherished memorial services. Lantern floating, as a ceremony, is an ancient and cross-cultural tradition that allows a community to share in the moment of remembering and honoring those we've lost by lighting a candle in their honor. The candles, which are set in a floating lantern, are set free at dusk in a symbolic gesture to be embraced by the wind and open waters. As the glowing lanterns float peacefully away from the devotee, the lantern joins countless other lanterns adrift together united by a synchronized gesture of aloha, peace, life, and love (Figure 31). While the floating lanterns are set free in a contained section of waters off of Ala Moana Beach Park and collected before entering the open ocean, the effect is still lasting and powerful. Lantern Floating Hawaii is a unique "water consolatory" ceremony that unites people from an array of religions, cultures, ethnicities, socio-economic backgrounds, and generations around a spiritual act that is centered on universal beliefs and emotions. According to the Nā Lei Aloha Foundation website (2013), "Lantern Floating Hawaii helps to open our hearts in an experience that transcends the human boundaries that usually divide us." The ceremony, now in its 16th year, attracts upwards of 50,000 participants from all walks of life to Ala Moana Beach Park every Memorial Day. Mr. Roy Ho, Executive Director of Nā Lei Aloha Foundation, was interviewed by Kimberly M. Mooney of Pacific Legacy, Inc. at the Nā Lei Aloha Foundation headquarters in Honolulu on 10 September 2013.

Figure 31. 2013 Lantern Floating Ceremony at Ala Moana Beach (photo courtesy of Nā Lei Aloha Foundation).

While the Lantern Floating Hawaii ceremony is open to the general public, its roots are grounded in Buddhism. According to Mr. Ho, Nā Lei Aloha Foundation is the "secular, community-building arm" of the Shinnyo-en Buddhist Order in Hawai'i. The foundation supports and gives contributions to a diverse group of charities and humanitarian causes in

Hawai'i. The name, Nā Lei Aloha, Hawaiian for "many lei of aloha," was given to the foundation in 2004 by the late, dearly loved Native Hawaiian cultural practitioner, Kupuna Aunty Malia Craver, on behalf of the foundation's mission of "bringing people together in cooperation and harmony" (Nā Lei Aloha Foundation website 2013). Shinnyo-en is a relatively new but International Buddhist sect that is founded on ancient Buddhist teachings in the Japanese Shingon tradition. Mr. Ho states that the term s*hinyo* denotes "truth" or "spiritual awakening" and *-en* stands for "borderless garden." When both terms are combined, the expression embodies the following concepts: "truth beyond all temporal boundaries" or "truth open to everyone." Master Shinjo Ito, the late founder of Shinnyo-en, wanted to help people to awaken and attain enlightenment as Siddhartha did over 2,500 years ago, but not through countless lifetimes and reincarnations. In Shinjo's teachings, which are begotten from the Nirvana Sutra (thought to be by many as the Buddha's final teachings), enlightenment can be attained by all people who simply hold to a path of genuine altruism following the four key virtues of "lovingkindness, compassion, joy, and equanimity" (Shinnyo-en website 2013).

According to Mr. Ho, Her Holiness Shinso Ito, Head of the Shinnyo-en Buddhist community and daughter of Master Shinjo Ito, wished to foster cultural harmony and understanding in Hawai'i by organizing and enacting a lantern floating ceremony. The ceremony she created is based upon the Japanese tradition of lantern floating in the final stages of the Obon festival, which is ritual to honor ancestral spirits. While the Lantern Floating Hawai'i ceremony is held every Memorial Day, a federally observed holiday created to honor fallen military personnel, the lantern floating ceremony is designed to honor all of our departed loved ones. To promote inclusivity, the Lantern Floating Hawai'i ceremony is preceded by traditional cultural practices from various religions and cultures, including Native Hawaiian *oli* and *hula*. Further, Nā Lei Aloha Foundation provides free floating lanterns (one per family) to all that wish to participate, but also encourages devotees to make their own vessel to impart the vessel with their own energy and essence.

The first officiated the inaugural Lantern Floating Hawai'i ceremony was enacted on Memorial Day in 1999 with approximately 7,000 participants. The Lantern Floating Hawai'i ceremony was held annually at Ke'ehi Lagoon for its first three years, before being moved to Ala Moana Beach a few miles to the east where it has been observed every year since. Approximately 50,000 people from all walks of life were estimated to have participated in the 2013 Lantern Floating Hawai'i ceremony, which attests to the universal attraction and inclusivity of the ceremony. It is likely that the number of participants will continue to grow.

Enduring to maintain the spiritual integrity of the ceremony without harming the environment or burdening city services, Nā Lei Aloha Foundation/Shinnyo-en - with the help of members and volunteers - organizes and facilitates the event in its entirety. Mr. Ho explained that Nā Lei Aloha Foundation works with the City and County (C & C) of Honolulu and other groups, but takes full responsibility for the event. All donations to Nā Lei Aloha Foundation/Shinnyo-en for the event specifically are given to the C & C of Honolulu for any impacts caused by the ceremony. Many measures are implemented before and after the ceremony to prevent environmental impacts. The foundation prepares the ceremonial space by leading volunteers in a massive park and beach cleanup prior to setting up ceremonial and event structures. The foundation also sets out catchment lines offshore to keep the lanterns from floating beyond

reach and harming marine life. Following the ceremony, members of the foundation and volunteers carefully collect the floating lanterns, which are transported to a sanctified space and burned in a final ritual. Despite the rising number of participants over the years the ceremony has had no regrettable incidents, perhaps a factor in its growing popularity.

As with other major events at Ala Moana Park, access and parking for those coming from other areas on the island to participate in the Lantern Floating Hawai'i ceremony remains key. In regards to potential impacts caused by the proposed Kaka'ako TOD Overlay, Mr. Ho declined to comment.

Community Consultation: Ms. Michelle Wong – Hawai'i Dragon Boat Festival

The Hawai'i Dragon Boat Festival has become a major two-day festival that takes place each summer in Ala Moana Beach Park annually (Figure 32). The festival, which is open to the public, consists of several events, with Dragon Boat racing as the main event and other festivities such as grass volleyball tournaments, cultural exhibits, live local entertainment, and big screen feature movie, as well as local craft and food vendors. This family friendly event has grown to over 4000 participants since its establishment start in 1996. Michelle Wong, representing the Hawai'i Dragon Boat Association, contributed information on the Hawai'i Dragon Boat Festival in several emails, phone calls, and online questionnaire in August 2013.

While Dragon Boat Racing has become a contemporary world-wide sport and recreational activity, it is an ancient Chinese tradition that originally functioned as a means to commemorate the life and teachings of Qu Yuan, a beloved warrior poet, who committed suicide over 2000 years ago. According to the International Dragon Boat Federation (IDBF),

> The Dragon has a very symbolic meaning for the Chinese. A classic dragon has the head of an ox; a deer's antlers; the mane of a horse; the body and scales of a snake; the claws of an eagle and the tail of a fish. With its strength and power the Dragon rides the clouds in the sky and commands the wind, mist and rain.
>
> The Dragon Boat is deeply embedded in China's 'Dragon' culture, with each Boat having an ornately carved dragon's head at the Bow and a tail in the Stern. The Hull is painted with the Dragon's scales. The paddles symbolically represent the claws. In IDBF Sport Racing there are generally 18-20 paddlers per Standard size Dragon Boat and 8-10 paddlers in the Small Boat, plus a drummer and a helm (Steerer). In Traditional Festivals the boat designs and crew numbers can vary from 10 up to 50 or more paddlers, plus of course the Drummer and Helm.
>
> The races are a colourful spectacle, with at least two boats competing against each other over distances from 200 to 2000 metres and above. Not only are strength, endurance and skill important but teamwork and harmony of purpose.
>
> In ancient China the Dragon Boat was used for religious purposes as a way of appeasing the rain gods. Later Qu Yuan, the great warrior poet, committed suicide in the river Mi Lo, as a protest against the political corruption of the day. To commemorate this sacrifice the people began to organize Dragon Boat Races in his memory. Since that time over 2000 years ago, Dragon Boat Racing has become a major part of Chinese culture, representing patriotism and group integrity (IDBF 2013).

Figure 32. Dragon Boat at Ala Moana Beach Park (photo courtesy of Hawai'i Dragon Boat Association).

In keeping with tradition, teams of colorful dragon boat racers power their canoes forward in sync with the rhythm of pounding drums at the Hawai'i Dragon Boat Festival. According to Ms. Wong, "Former Mayor Jeremy Harris and the late Honorary Mayor of China Town Mr. Sun Hung (Sonny) Wong were able to secure the donation of 3 traditional Dragon Boats from Honolulu's Sister City, Kaohsiung. With the 3 boats, the Festival has continued to grow to include other sports such as volleyball to attract more people, both native and visitors, to join together in participation, camaraderie, and a lot of fun" (M. Wong 2013). She adds that the Hawai'i Dragon Boat Festival held at Ala Moana Beach Park are enjoyed by a wide variety of groups, including "local cultural based organizations to Hawaiian and national organizations and companies" (M. Wong 2013). Ms. Wong holds that the Dragon Boat Festival is significant to the community, as it brings a lot of people together as a group, which "…enhances public enjoyment and appreciation of Ala Moana Park and makes Honolulu a more exciting place because there are different and unique events going on" (M. Wong 2013). The community, according to Ms. Wong, consists of people from many areas outside of Kaka'ako as well as within, stating:

> People come from different areas for the event. It is events and activities such as this that make the Community a great place to be. These events attract people,

> and with the greater number of people coming to the area there will be more commerce, whether it is the gas used for transportation to the site or the food and supplies the people bring or purchase for the event (M. Wong 2013).

Thus, the 17 year running annual Hawai'i Dragon Boat Festival brings people together from all over O'ahu, and perhaps beyond, to participate in an ancient Chinese festival that now integrates contemporary sports and recreational themes that appeal to people of all walks of life.

In regards to potential impacts caused by the proposed Kaka'ako TOD Overlay, Ms. Wong feels that there should be no impacts to the Hawai'i Dragon Boat Festival held at Ala Moana Park, unless as she states, "it takes away the park and surrounding parking" (M. Wong 2013).

5.3.6 Irwin Memorial Park

Across Bishop Street of the HECO Downtown Power Plant portion of the project area is Irwin Memorial Park, which was constructed in 1930. This park is approximately two acres of open shaded grass lawns with a long promenade running *mauka* to *makai* through the center and an inoperable water fountain at its heart (Figure 33). The park offers a choice location with numerous concrete tables and stools, which encircle the water fountain. No cultural activities were identified as occurring at the park through documentary research. A site inspection performed on 10 August 2013 by Kimberly M. Mooney of Pacific Legacy, Inc. failed to identify any specific cultural practices occurring at the park, though being one of the few open space parks in the area, the likelihood of cultural activities occurring at Irwin Memorial Park is high.

Figure 33. Non-operational Water Fountain at Irwin Park (view to north).

5.3.7 Thomas Square

Historic Thomas Square is a 6.5 acre open space park located across King Street of the northern border of the Kaka'ako TOD Overlay project area. This park, dedicated in the 1840s, is registered in the State and National Register of Historic Places (Reference No. 72000423; State Site No. 80-14-9990) due to its role in Hawaiian history as the location that Kamehameha III held a ceremony to reinstate the Hawaiian Kingdom's sovereignty after being temporarily overtaken by the British Lord, George Paulet. According to the Thomas Square NRHP Nomination Form:

> In early 1843, Lord George Paulet, representing the British Crown, overstepped his bounds, landed sailors and marines, seized the government buildings in Honolulu and forced the King (Kamehameha III) to cede the Hawaiian kingdom to Great Britain. Paulet raised the British flag and issued a proclamation formally annexing Hawaii to the British Crown. Queen Victoria, on learning the injustice done, immediately sent an envoy to the islands to restore sovereignty to its rightful rulers. The man chosen for this task was Rear Admiral Richard Thomas, and on July 31, 1843, pompous ceremonies were held whereby the Hawaiian Kingdom was restored. It was on the occasion of the restoration that Kamehameha was moved to say, "Ua mau ke ea o ka aina i ka pono" -- The life of the land is restored in righteousness. (This statement has since become the official motto of the State of Hawaii.)
>
> From July 31, 1843, the plot of land on which the ceremonies took place was known as Thomas Square. Kamehameha III later officially gave this, name to the area and dedicated it as a public park. In 1850, the Privy Council voted to enlarge the square, and in 1925, a Joint Resolution of the legislative session set aside Thomas Square as a public park and placed it under the management of the Park Board of the City and County of Honolulu. It remains this today (NRHP 1972:3).

In addition to being historically significant, Thomas Square is currently used for a variety of cultural practices and events (Table 19). The annual Honolulu Intertribal Powwow held by the Northern Cherokee Nation has been ongoing since 1974. The Honolulu Intertribal Powwow website describes the event as follows:

> The first ever Honolulu Intertribal Powwow began in October 1974 with a small group of interested Native American individuals who longed for a place to celebrate their culture through music, drumming, dance, food and sharing their native arts and crafts. Many of them either came to Honolulu via military service, had family members who left their reservations and inter-married with native Hawaiians and other diverse ethnicities in the islands, or through adoption and being raised in an island culture and far from their native reservations (Honolulu Intertribal Powwow 2013:home).

Several Native Hawaiian events also take place annually at Thomas Square that are culturally significant, including the Hui Mau Ke Ea gathering and Ilima Kumu. A high frequency of dog shows take place at Thomas Square, which can be considered cultural practices for those within the dog enthusiast communities.

Table 19. Thomas Square Permitted Activities and Events for 2013

Organization	No. of days	No. of Attendees	Total	Purpose
Aloha State Sporting Dog Assn	2	100	200	Dog show

Ongoing: non-permitted but coordinated with Dog clubs	250	10	2500	
Totals	**39**	**4550**	**11295**	

5.4 MEMORIALS AND COMMEMORATIONS

A total of four memorials and commemorations have been discovered within or adjacent to the Kaka'ako TOD Overlay project area that have not been identified in previous CIA.

5.4.1 Ehime Maru Memorial

The Ehime Maru Memorial, located in Kaka'ako Waterfront Park, was dedicated on 9 February 2002 to honor the victims of the disastrous accidental sinking on 9 February 2001 of the Ehime Maru, a Japanese Fishery High School training ship, after its collision with the US Navy submarine, the USS Greenville (Figure 34). The tragic event is thoroughly described in the National Transportation Safety Board's "Marine Accident Brief: Collision between the U.S. Navy Submarine USS Greeneville and Japanese Motor Vessel Ehime Maru near Oahu, Hawaii, February 9, 2001" (NTSB 2013), which is provided in Appendix G.

Figure 34. Ehime Maru Memorial at Kaka'ako Waterfront Park (view to south).

Community Consultation: Mr. Ed Hawkins - Ehime Maru Memorial Association

Mr. Ed Hawkins, President of both the Ehime Maru Memorial Association (EMMA) and the Japan-America Society of Hawai'i (JASH), contributed information regarding the Ehime Maru Memorial and EMMA's role in maintaining the memorial via telephone communications, emails, and online questionnaire from July through August of 2013.

The Ehime Maru Memorial was designed by Uwajima Fisheries High School graduate, Kyosuke Tamai and is composed of nine black granite blocks that support the Ehime Maru's salvaged one-ton anchor with nine links of its chain still attached. Engraved in stone in English and Japanese is the following inscription: "This honors the nine precious lives lost and serves as a place where their souls are remembered" as well as the names, titles, and ages of the nine victims, a summary of the tragic event, the school emblem, and a map showing the accident site,

the site of the Navy's recovery effort, the ship's final resting place as well as the Aloha Tower. The memorial is surrounded by stainless steel bollards and chains.

According to Mr. Hawkins, the Ehime Maru Memorial was erected a year after the catastrophic incident. The formal memorial service is held annually on the day of the tragic event for "…bereaved family members, representatives from the city of Uwajima in Ehime Prefecture (home port of the Ehime Maru), Ehime government representatives, representatives of the U.S. Navy, and Hawaii residents" and "…is attended by Hawaii's Governor and Mayor of City of Honolulu and their representatives)" (Hawkins 2013). Since its inception in November 2001, EMMA arranges two professional cleanings a year and volunteer cleaning weekly, which is carried out by Japanese-American groups (Kenjinkai, Honolulu Japanese Chamber of Commerce), Japanese student visitors, Japan Self Defense Forces personnel who visit Hawai'i. He further states that EMMA provides the maintenance through a stipend provided annually by the Ehime Prefecture government" (Hawkins 2013). Thus, the victims of the Ehime Maru's accidental sinking are still honored at this memorial regularly.

Mr. Hawkins holds that "As long as the subject development does not interfere with the annual memorial service" in regards to potential impacts caused by proposed Kaka'ako TOD Overlay. Further, he states that "Cleaning arrangements can be adjusted based on the development schedule" (Hawkins 2013).

5.4.2 MADD Memorial

The Mothers Against Drunk Driving (MADD) Victim Memorial was created in March of 2003 to remember individuals who were injured or lost their lives in impaired driving crashes (Figure 35). Regular visits, ceremonies, and candle light vigils at the memorial continue to serve the bereft and honor the victims of drunk driving incidents as well as violent crimes. The MADD Victim Memorial is located at the Ewa end of Kaka'ako Waterfront Park, behind the John A. Burns School of Medicine, and is designed to accommodate large groups, long visits, and disabled visitors.

Community Consultation: Ms. Abigail Nickell - MADD Hawai'i Victim Memorial

Ms. Abigail Nickell, Executive Director of MADD Hawai'i, shared information regarding the MADD Victim Memorial via emails and an online questionnaire during July and August of 2013.

Ms. Nickell stated that, "During MADD Hawai'i's 15th anniversary commemoration in March 1999, a dream was born to give our community a victim memorial to remember individuals who were injured or who had lost their lives in impaired driving crashes and other violent crimes" (Nickell 2013). She holds that such a memorial was essential for the community, stating:

> All over the world, victims of highway crashes die relentlessly every day, every month, every year. Most likely they are unpublicized deaths, only occasionally attracting the attention of the press. But those left behind experience the same horrible, traumatic grief known to all those losing a loved one in a sudden violent criminal act. MADD believes these victims deserve to be remembered and their families deserve to have a special place to visit, reflect, and mourn… MADD believes the community deserves to see a tangible reminder of the senseless deaths of so many of its citizens in order to remember that we all have the power to stop these tragedies (Nickell 2013).

Hence, the MADD Victim Memorial stands to honor the victims, but also stands as a reminder to the community at large of the absolute and detrimental effects that drunk driving and other violent crimes can have on fellow citizens.

Figure 35. MADD Victim Memorial at Kaka'ako Waterfront Park (view to northwest).

The dream of a victim memorial was realized in March of 2003 with former Governor Linda Lingle, former First Lady Vicki Cayetano, MADD National President Wendy Hamilton, and bereaved father, Mr. Robert Gore speaking for the dedication of the sculpture. John Tanji Koga, an esteemed Honolulu sculptor, lent his talents to create the 13-foot high abstract sculpture of three adjoined family members, each with mid-chest circular voids. As Ms. Nickell elucidates, "The bronze work poignantly depicts a family trio, each with a void where the heart would have been. Years may go by but the emptiness in the hearts of victims' families will always remain" (Nickell 2013).

Ms. Nickell holds that as long as a peaceful atmosphere is maintained at the MADD Victim Memorial, it will not be negatively impacted by the proposed Kakaʻako TOD Overlay. She states, "Developing the area could potentially bring more foot traffic to the memorial and more attention to the dangers of drunk driving and other violent crime, which would be wonderful. We would hope that the increased development would not significantly change the peaceful atmosphere of the Victim Memorial, as it was designed to be a place of reflection, remembrance, and mourning" (Nickell 2013).

5.4.3 Nagasaki Peace Bell

The Nagasaki Peace Bell is located on the Frank F. Fasi Civic Grounds of Honolulu Hale (City Hall), along Beretania Street near Lauhala Street, which is one block to the northwest of the proposed Kakaʻako TOD Overlay project area. The monument was dedicated on 7 December 1990 with a delegation of more than sixty Nagasaki Hibakusha, or surviving victims of the Nagasaki atomic bombings, in attendance. While the primary function of the monument is for honoring all victims of the atomic bombings at Nagasaki as well as an acknowledgment of harmful actions played out during World War II, the Nagasaki Peace Bell has also come to be associated with Dr. Martin Luther King, Jr., a world renowned peacemaker and promoter of non-violence. Since its erection, every year the bell has been rung ceremonially on August 9th in remembrance of the Nagasaki atomic bomb victims and on the third Monday of January each year for Martin Luther King Jr. Day to protest the manufacture and use of nuclear weapons.

Community Consultation: Ms. Marsha Joyner - Nagasaki Peace Bell

Ms. Marsha Joyner, Co-Chair of the Nagasaki Peace Bell Ringing Ceremony, provided information through emails and telephone communications in July 2013.

The Nagasaki Peace Bell is a replica of the bell from the tower of Urakami Cathedral in Nagasaki, Japan, which is a bronze bell that is suspended by four steel supports and topped with a life-sized bronze sculpture of a flying crane. According to Ms. Joyner, the bell was a gift to City and County of Honolulu from the City of Nagasaki, Japan.

Participants in the 2013 Nagasaki Peace Bell Ringing Ceremony consisted of the Dr. Martin Luther King, Jr. Coalition – Hawaiʻi, The Royal Hawaiian Band, Friends of the Gensuikin, Nagasaki Kenjinkai (Association of Descendants of Immigrants from Nagasaki Prefecture), United Nations Association Hawaiʻi Chapter, International Peace Poem Project, and the Chamber of Commerce for Persons with disABILITIES – Hawaiʻi as well as the general public.

5.4.4 Florentino Das Commemorative Plaque

Over twenty years before the epic voyage of the Hōkuleʻa from Hawaiʻi to Tahiti, Florentino Das set off on his trans-oceanic solo voyage from Kewalo Basin, Oʻahu, to his native Philippines on 14 May 1955. A commemorative plaque has been installed at Kewalo Basin Park to honor this brave Filipino (Figure 36).

Figure 36. Florentino Das Commemorative Plaque at Kewalo Basin Park (close up).

Community Consultation: Dr. Serafin Colmenares - Florentino Das Story

Scholar on the life and achievements of Florentino Das and co-author of the book, *Bold Dream, Uncommon Valor: The Florentino Das Story* (Colmenares et al. 2013), Dr. Serafin Colmenares contributed further information on Mr. Das and his sentiments on the importance of the memorial plaque at Kewalo Basin via emails, online questionnaire, and personal exchanges.

Florentino Das was born in Allen, Northern Samar Island, Philippines in 1918 and came to Hawaiʻi in 1934 at the age of 16 as a stowaway on a British freighter heading to the United States. Das survived initially in Hawaiʻi doing various odd jobs and eventually he became a boat builder, carpenter, and mechanic as well as a noted prize-fighting boxer. He married and raised a family in Māʻili, Oʻahu, while working at the Pearl Harbor shipyard. Despite his accomplishments in Hawaiʻi, Mr. Das felt compelled to make a pilgrimage back to the Philippines for several reasons: to provide a brighter future for his family in Hawaiʻi, to help the family he left in Samar, and for Filipino pride (Colmenares et al. 2013: 28).

To make the journey, Florentino modified a 24 foot wooden boat by hand for trans-oceanic voyaging and renamed the vessel, Lady Timarau, which was powered only by a canvas sail and two 25-hp outboard motors for maneuvering in harbors. On 14 May 1955, Das began his voyage from Kewalo Basin, Oʻahu, to his homeland, the Philippines. Navigating only by the stars and a simple compass, Mr. Das was able to cross 5,000 miles of the Pacific through numerous storms in just under a year with no means to communicate with the rest of the world. After a few stops in Micronesia, the Lady Timarau landed on Siargao Island in the province of Mindanao, Philippines on 25 April 1956, before continuing on to his birthplace of Northern Samar Island, Philippines. Although he was advised by his sponsors to abort his mission, Mr. Das refused to give up, as he believed that Filipino national pride was at stake. Upon his arrival in Manila, Florentino Das was welcomed by his homeland and honored by Philippine President Ramon Magsaysay with the honorary title of Commodore of the Philippine Navy as well as the Legion of Honor. However, no honors were given to Mr. Das in Hawaiʻi and his triumphant voyage was celebrated by few. The fanfare over his accomplishment eventually faded in the Philippines and Florentino Das' fame and affluence waned as did his health. Mr. Das succumbed to illness and passed away in Manila on October 7, 1964, at the young age of 46 - never to return to his family in Hawaiʻi (Colmenares et al. 2013).

A commemorative plaque was dedicated to Florentino Das at the main pavilion of Kewalo Basin Park in 2006 as one of the major activities undertaken by the Filipino community during the centennial celebration of Filipinos' arrival in Hawaiʻi, according to Dr. Colmenares. The production and installation of the plaque was initiated and implemented by the Congress of Visayan Organizations through the Filipino Centennial Celebration Commission and approved by the Hawaii Community Development Authority. As Florentino Das was a Filipino of Visayan origin, Dr. Colmenares holds that it was a fitting tribute for the members of the Congress of Visayan Organizations (COVO) and the Oahu Visayan Council to bestow on behalf of one of their own. The memorial highlights one of the major achievements of the Filipino community in Hawaiʻi and, thus, is a significant cultural resource for all Filipinos. According to Dr. Colmenares, "the plaque symbolizes the triumph of hope over adversity. It showed that dreams can be fulfilled. It proved that the Pacific can be conquered, and is an example of how the Pacific peoples might have traveled across the vast oceans - certainly a forerunner of the Hokuleia and other present-day voyaging activities" (Colmenares 2013).

The Florentino Das Commemorative Plaque is a bronze embossed tablet that is mounted on a north facing pillar at the central opening of the main pavilion of Kewalo Basin Park (Figure 36). The 18 inch by 24 inch plaque describes Mr. Das' solo voyage from Kewalo Basin to his native Philippines as well as a short biography of Mr. Das and a depiction of his vessel, the Lady Timarau.

Regarding the proposed Kakaʻako TOD Overlay, Dr. Colmenares believes that the project may increase the chances for the site to become a tourist destination (Colmenares 2013).

5.5 Religious and Spiritual Gathering Places

A total of eleven Religious or Spiritual Gathering Places were identified within or adjacent to the Kakaʻako TOD Overlay project area. These institutions provide a space for public worship, ceremonies, celebrations, atonement, and/or spiritual reflection, which are cultural practices for those within a spiritual community or religious sect. Of the eleven Religious or Spiritual Gathering Places, 4 long-standing institutions were identified and described below.

5.5.1 First Chinese Church of Christ

The First Chinese Church of Christ is located on 1054 South King Street and located across South King Street of the project area. The main structure of the church was built in 1929 and is a novel integration of Chinese and Western architectural styles. In addition to its contemporary cultural use, the antiquity of the Church and unique architecture suggest that this church is eligible for NRHP status. The church has an active congregation and meets regularly on Sundays for worship.

5.5.2 Kawaiahaʻo Church

Kawaiahaʻo Church, located in the northwest corner of the project area, is a component of the Hawaiʻi Capitol Historic District, which is on the State and National Register of Historic Places (NRHP Reference No. 78001020; State Site No. 80-14-1321). A full description of the Historic church is provided in the NRHP Nomination Form (NRHP 1978b), which is provided in Appendix E. Since its erection in the early 1840s, Kawaiahaʻo Church has been the center of cultural events for the entire island community. Kawaiahaʻo Church continues to be a favored setting of important events and ceremonies. The Church and its grounds have been recognized in previous CIA as culturally significant in the past. However, it is important to note that Kawaiahaʻo Church remains to be a major cultural hub for Christians as a cultural group and for the general community of Kakaʻako. The church hosts regular and special events that are open to the community, such as craft fairs, physical fitness classes, youth programs, and Christian based education programs. Site inspections of Kawaiahaʻo Church on the 2nd and 22nd of August verified the contemporary cultural usage of the church and its grounds.

5.5.3 Ke Alaula Oka Malamalama

The Ke Alaula Oka Malamalama (The Bright Morning Rays of the Church of Reasonable Service) is located at 910 Cooke Street. According to (Ritz 2002) the church, which is a mixture of Protestant and Hawaiian faith, is one of the oldest churches in the state. She holds that the Founder, Reverend J.H. Poliwailehua, was called to faith in 1853 and initiated the Christian sect in the 1880s. It is said that Queen Liliʻuokalani preferred this church to Kawaiahaʻo (Ritz 2002). To this day, the sermons are mostly delivered in Hawaiian as are the hymns. The church continues to serve the community of Kakaʻako and has a congregation of approximately 300 hundred members.

5.5.4 Makiki Christian Church

Makiki Christian Church is located at 829 Pensacola Street, which is situated in the northeast corner of the project area. The Makiki Christian Church was added to the State Register of Historic Places (Site No. 80-14-9719) in 1988 and was identified as a cultural resource in

Spearing et al. (2008) as a Historic structure in Kakaʻako. However, no mention was made about its current cultural significance. This church has been in operation since 1904 and continues to serve the community of Kakaʻako in Japanese and English.

5.6 Public Art Installation & Entertainment Centers

While Kakaʻako has a colorful past, people who live, work, and travel from afar have come to identify Kakaʻako as its own district with a progressive, freethinking, and counter-culture atmosphere. Kakaʻako has, among many, a growing urban culture that is united by the arts (i.e. visual, musical, & performing) and is fast becoming what the community of Kakaʻako identifies with. As a result, Kakaʻako has become a vital hub for the modern arts movement in Hawaiʻi. Artists and art enthusiasts are beginning to flock to Kakaʻako for the many cultural resources it has to offer. Several public art installation and entertainment centers provide the general public access to art and artists a venue to share art, which are both important cultural practices.

5.6.1 POW! WOW!

POW! WOW! is a year round contemporary and Urban arts movement, which is centered around a week-long mural festival in Kakaʻako held annually in mid-February. The main POW!WOW! event has grown to unite over a hundred international and local artists in the creation of murals and other art forms at various publicly viewable locations of Kakaʻako (between Queen Street and Ala Moana Boulevard)(Figures 37 and 38). Since its inception in 2010, POW! WOW! as an organization has developed into a global network of artists and has put together dozens of local arts exhibits, lecture series, mural projects, concerts, a school for visual art and music, and a large creative space named Lana Lane Studios. POW! WOW! is also responsible for organizing several live art installations across the globe.

Community Consultation: Mr. Jasper Wong - POW! WOW!

Jasper Wong, Founder and Lead Director of POW! WOW!, contributed information about the arts organization via emails and online questionnaire between July and August 2013.

According to the organization's website, the name POW!WOW! was chosen for the organization based upon the following ideas:

> POW! – It's the impact that art has on a person. A punch in the face.
> WOW! – It's reaction that art has on a viewer. A sense of awe and wonderment.
>
> Together they form POW! WOW!, which is a term that describes a gathering that celebrates culture, music and art (J. Wong 2013b).

In 2010, Mr. Wong held the first POW! WOW! Urban mural art event in Hong Kong as a means of creative expression for himself and other Urban or Street artists. In organizing the event, he formed a collective of artists, together starting a gallery that is still in operation in the city of Hong Kong. POW! WOW! 's main event in 2013 had expanded to include 100 artists hailing from Hawaiʻi as well as Austria, South Africa, Japan, Australia, and UK creating 40 murals in Kakaʻako over the span of a week. As POW! WOW! heads into its fifth year, Wong plans to expand "across the nation and globally" (J. Wong 2013a). Locally, POW! WOW! has become a

major player in the growing arts movement in Kakaʻako, contributing many significant visual landmarks in the evolving cultural landscape of Kakaʻako.

POW! WOW! is a multifaceted arts collective and cultural resource, that provides "artistic expression, cultural sharing, and beautification of a neighborhood through art" for the community (J. Wong 2013a). It also educates the community at large, especially its youth, about contemporary Urban or Street art and its importance as a legitimate form of expression in a community such as Kakaʻako. POW! WOW! offers several unique youth educational programs that highlight urban art and culture in a safe, legal setting. Another significant aspect of POW! WOW! to the local arts community is that it helps support the arts economically and connects Hawaiʻi to a greater community of international artists as well as the global economy (J. Wong 2013a).

According to Mr. Wong, POW! WOW's School of Art is a collective effort between POW! WOW! and 808 Urban, where students from local schools participate in a nine month art centered mentorship program (J. Wong 2013a). Art workshops, held by 808 Urban's John "Prime" Hina, are available through this program weekdays after school and on Saturdays in Kakaʻako's industrial district. The workshops are designed to do the following:

> ….explore contemporary urban art and its influence on commercial culture from the 1950s to the present…Students will discuss changing societal concepts regarding contemporary public "street" art while exploring a variety of artistic concepts, including basic design, color theory, and symbolism. Additional elements that will naturally come from these workshops include self-expression, and cultural awareness, as well as respect for community and nature. These workshops are an effort to prepare students for future POW! WOW! Hawaiʻi gatherings. The more art these students do in preparation for these gatherings, the more the students will be able to learn from these national and international urban artists. The hope is that the participating students will be able to conceive, develop, and collaborate on a large mural in Kakaʻako as part of POW! WOW! Hawaiʻi…The ultimate mission is to validate student art experiences and introduce young people to various forms of public expression. Working closely with 808 Urban to continue to support a gathering of contemporary artists that engages with the broader community in the process and creation of art. The final product of the project will beautify a portion of the students' urban landscape (J. Wong 2013a).

Schools that have participated in POW! WOW!'s education program include Kamehameha Schools, Roosevelt High School, McKinley High School, Voyager Charter School, Punahou School, Farrington High School, Mid-Pac Schools, Maryknoll School, La Pietra School, and Washington Middle School as well as the YMCA (J. Wong 2013a).

POW! WOW!'s School of Music partners with Flexfit, LLC, a global custom hat vendor, to provide Hawaiʻi's youth with a unique music education program that offers a select group of local musicians between the ages of 13-18 the opportunity to learn composition, vocals, percussion, guitar, ukulele, keyboard, bass, recording, performance and the music business from local and international musicians and music industry professionals. Through this

program, students have the opportunity to collaborate with one another to create original music and have the opportunity to perform for the public at the conclusion of POW! WOW! Hawai'i's main event (J. Wong 2013a).

Figure 37. ***The Hawaiian Gods Wall*****, created by artists, Prime, Estria, Trek6, and Mike Bam (photo courtesy of POW!WOW!).**

Figure 38. The Mahalo Wall, created by artist Eric Marcinizyn (photo courtesy of POW!WOW!).

Mr. Wong holds that the proposed Kaka'ako TOD Overlay may have a positive effect as well as negative impacts on POW! WOW!'s programs and events. "An increase in viewers of the murals and participation in related initiatives and activities…" as Mr. Wong (2013a) states, would benefit POW! WOW! Hawai'i. Yet, he holds "…increased property value might lead to less owners open to art on their property," which would cause considerable impacts to the organization.

5.6.2 Neal S. Blaisdell Concert & Exhibition Complex

The Neal S. Blaisdell Concert and Exhibition Complex, most commonly referred to as 'The Blaisdell,' is located on 777 Ward Avenue and situated centrally within the project area. The complex is comprised of a multi-purpose arena, exhibition hall, galleria, concert hall, meeting rooms, and parking structure. Since 1964, the Blaisdell has provided the island of O'ahu with 'big ticket' entertainment and access to arts and culture on a scale almost unmatched in the state. The complex is nearly eligible for NRHP status.

5.6.3 FreshCafe & Loft in Space

The Fresh Cafe and Loft in Space located at 831 Queen Street, Kaka'ako are adjoined venues that provide a space for social interactions and creative collaboration primarily within the arts community. The Fresh Cafe is principally a café that sells local and/or healthy fare, coffee, tea, juices, and smoothies, but its main allure is that it has become a hub for creative minds in Kaka'ako. The creators of Fresh Cafe eventually expanded the venue for these meetings-of-the-minds, opening the Loft in Space, a renovated warehouse loft at the rear of Fresh Cafe to host art exhibits, workshops, and performances.

<u>Community Consultation: Mr. Jasper Wong - Fresh Cafe and Loft in Space</u>

Jasper Wong, Co-owner of Fresh Cafe and Loft in Space, provided details of the joint venues through email communications and online questionnaire in August 2013.

According to Mr. Wong, Tiffany Tanaka, Founder of Fresh Cafe and Loft in Space, saw a need for a cafe/venue space in Kaka'ako for the arts. Mr. Wong partnered with Ms. Tanaka to open the creative arts center in July of 2009 (J. Wong 2013c). As stated by the Fresh Cafe website, "Fresh Cafe was born into the hip and up and coming industrial district of Kaka'ako. [Fresh Cafe is a] hidden oasis with an eclectic mix of artists, students, musicians, and entrepreneurs who need to get away from the hustle and bustle of the city" (Fresh Cafe 2013). Further, the website holds that The Fresh Cafe mission is as follows:

> …to provide a unique gathering space for the community by offering healthy food choices and showcasing both up-and-coming and major talent in music, art, and cuisine. We strive to promote creativity, sustainability, local business, and Fresh ideas. We are here for the next-level dreamers, fearless innovators, and dedicated visionaries. We dare to inspire and be inspired (Fresh Cafe 2013).

Thus, the Fresh Cafe is not only one of the few locations where the community of Kaka'ako can purchase local and/or healthy foods and beverages, it functions for many as a refuge from the stress of city life as well as a sharing and collaboration space for various forms of art being

produced locally. The mission of Loft in Space is to be a "community space supporting the visual arts, music, and education on an international and local scale," which is "…dedicated to the cultural enrichment of the community…" (Loft in Space 2013). To do so, exhibitions, outreach, and related educational programs are held at the Loft in Space monthly. Therefore, the Loft in Space shares the same values as Fresh Cafe, but is an open, food free space to accommodate large gatherings and exhibits centered on the arts. While the Fresh Cafe and Loft in Space are open to all ages, regular customers and participants tend to range from teenagers and thirty-somethings (J. Wong 2013c).

Mr. Wong had a positive outlook on how the proposed Kaka'ako TOD Overlay will affect the Fresh Cafe and Loft in Space, stating: "Hopefully it brings more patrons to the cafe and events held at the space" (J. Wong 2013c).

5.6.4 Vacant Lots & Thoroughfares

Numerous properties within the Kaka'ako TOD Overlay project area have become regular outdoor venues where culturally significant events take place regularly. Table 20 lists the events, the locations, the frequency of the events, and the cultural groups they serve.

Table 20. Events Regularly Occurring in Vacant Lots & Thoroughfares

Event	Location	Frequency	Cultural Group/group
Art & Flea	831 Queen St.	Modern-ongoing, Monthly, 4th Thursdays	Contemporary/Urban Arts (visual, musical, fashion, & food) communities & enthusiasts; community members (no specific ethnic group); local commercial groups; patrons (tourist & residents)
Eat the Street	555 South St.	Modern-ongoing: Monthly	Culinary arts & music communities & enthusiasts; community members (no specific ethnic group); patrons (tourist & residents)
Honolulu Night Market	683 Auahi St.	Modern-ongoing: Monthly	Arts/music, fashion, & food communities & enthusiasts; community members (no specific ethnic group); patrons (tourist & residents)
Honolulu 5K and 1 Mile Keiki Run/Walk	S. Beretania St. to S. King St.	Modern-ongoing: Annual	Running community; community members (no specific ethnic group); spectators (tourist & residents)
King Kamehameha Floral Parade	From corner of King St. & Richards St. to Kapiolani Park	1916-present; Annual (2 days in June)	Parade participants; Hawaiian community; community members (no specific ethnic groups); commercial groups; patrons, & spectators (tourist & residents)
Pow!Wow! Hawai'i	Various locations in Kaka'ako Mauka and Makai	Modern-ongoing: Annual (2 days in February)	Contemporary urban & music/arts community; community members (no specific ethnic group); patrons, & spectators (tourist & residents)
Three Walls Music Festival	311 Keawe St.	Modern-ongoing: Annual (2 days in May)	Contemporary & urban music/arts community; community members (no specific ethnic group); tourist & local spectators/ patrons

6.0 SUMMARY AND RECOMMENDATIONS

In the Final Environmental Impact Statement Preparation Notice (EISPN) for the Kaka'ako Transit Oriented Development (TOD) Overlay, Sichter (2012) states, "…persons most impacted by the Proposed Action will be existing and future residents of the district, together with all commuters who will pass through the district by car, bus, light rail, bicycle, or as pedestrians." (Sichter 2012:3). This Supplemental Cultural Impact Assessment (SCIA) prepared for the Kaka'ako TOD Overlay focuses on cultural resources in Kaka'ako that are utilized by the above mentioned persons and identified cultural groups.

To be inclusive of all cultural groups, including "Native Hawaiians, other ethnic groups, and other groups" (OEQC 1997: 3-4), and to address areas not previously assessed, this SCIA has added over thirty new cultural resources to the existing record of cultural resources for Kaka'ako. The existing record of cultural resources is based upon five Cultural Impact Assessments (CIA), two Ethno-Historical Inventory studies, and a Traditional Cultural Property (TCP) study that have been performed in the Kaka'ako area (UH 1978; Wilson Okamoto and Associates, Inc. 2002; McElroy et al. 2008; Spearing et al. 2008; Vogeler et al. 2010; Genz & Hammatt 2010; Elison and McElroy 2011; Maly et al. 2013).

A total of 34 cultural resources consisting of Historic Places and Landmarks (n=8), Cultural Learning Facilities (n=7), Public Parks and Grounds (n=7), Memorials and Commemorations (n=4), Religious and Spiritual Gathering Places (n=4), and Public Art Installation and Entertainment Centers (n=4) were identified in this SCIA (Table 16). A significant number of cultural resources (n=21) were identified as occurring within the project area and numerous resources occurring in areas adjacent to project area (n=13).

6.1 HISTORIC PLACES AND LANDMARKS

A total of eight Historic Places and Landmarks have been identified that were not previously identified in CIAs performed in the area, consisting of the following seven Historic properties located within or adjacent to the project area: Kawaiaha'o Church, Hawaiian Mission Houses, Kapuāiwa Building, Hawai'i State Library, Honolulu Hale, Honolulu Hale Annex, State (Territorial) Office, Hawaiian Electric Company (HECO) Downtown Plant, Aloha Tower, *Falls of Clyde*, Mabel Smyth Memorial Building, Post Office, Customhouse, and Courthouse Building (King David Kalākaua Building), Dillingham Transportation Building, and U.S. Immigration Office.

The Hawaiian Capitol Historic District, which contains Kawaiaha'o Church, Hawaiian Mission Houses, Kapuāiwa Building, Hawai'i State Library, Honolulu Hale, Honolulu Hale Annex, State (Territorial) Office, is currently active on the NRHP and State Register of Historic Places (NRHP Reference No. 78001020; State Site No. 80-14-1321); thus, protected by state and federal laws. Located within the project area are Kawaiaha'o Church and Hawaiian Mission Houses, both of which have historic and contemporary cultural significance. In the case of Kawaiaha'o Church, cultural practices, such as regular church service, visitation of the cemetery, and

ceremonial events continue to be important to the Island-wide community. The Hawaiian Mission Houses are repositories and active interpretive centers that continue to serve the community as well. While the Hawai‘i State Library, Honolulu Hale, and Honolulu Hale Annex are located outside of the project area, they are important institutions that have been serving the community for over a century. The Kapuāiwa Building and State (Territorial) Office are less important in terms of significant cultural usage in the modern era. As these properties are already protected by state and federal law, no impact is expected from the Kaka‘ako TOD Overlay. However, visual impacts from encroaching skyscrapers may occur if a sensible distance is not kept from these properties. In addition, access and parking is still an important necessity for the properties that carry contemporary cultural significance, such as Kawaiaha‘o Church, Hawaiian Mission Houses, Hawai‘i State Library, Honolulu Hale, and Honolulu Hale Annex. Reduction of public parking may be a resultant impact from Kaka‘ako TOD Overlay developments. It is recommended that parking and accessibility to these properties is not reduced in project related developments.

The 1929 Hawaiian Electric Company (HECO) Downtown Plant is located in the project area and is not yet recognized by the State of Hawai‘i or NRHP as a Historic site although it likely is eligible based on its antiquity, architecture, and historic significance. However, there were no signs of contemporarycultural utilization of the property and, therefore, no foreseen impacts as a result of the proposed action. It is recommended that the building be protected until the proper authorities evaluate its significance and submit a nomination form to NRHP and/or State Register of Historic Places.

The Aloha Tower, which continues to be an icon for the State of Hawai‘i, is adjacent to the Hawaiian Electric (HECO) Downtown Plant portion of the project area. Due to its cultural and Historic significance, it has been recognized by its NRHP and State Register of Historic Places status (State Site No. 80-14-9929 and NRHP Reference No. 76000660) for over thirty years. Potential impacts to this property may come in the form of visual impacts from increasing build up heights for properties located adjacent or near to the Aloha Tower. Current cultural usage consists of visitation of the interpretive displays within the structure, use of the observation deck located at the top floor of the structure, as well as a variety of commercial activities that occur in the surrounding Aloha Tower Market Place. Parking and access is also important to maintain. It is recommended that parking and accessibility to these properties is not reduced in future developments.

The *Falls of Clyde* is currently moored in waters adjacent to the Hawaiian Electric (HECO) Downtown Plant portion of the project area as well. The vessel is also registered under the NRHP (Reference No. 73000659) and State Register of Historic Places (Site No. 80-14-9700). While the vessel is under major repairs, thus not accessible to the public, it remains a significant nautical attraction on the coastal landscape. No impacts to the *Falls of Clyde* by the proposed action are foreseen. In the event that the vessel is fit for boarding by the public in an interpretive context, access and public parking should fit the demand of visitors.

Located in the southwest corner of the project area is the Mabel Smyth Memorial Building, which is currently registered with NRHP and State Register of Historic Places (Reference No. 93001558; State Site No. 80-14-9765). Yet, this structure has not been identified as a cultural

resource in previous CIAs. As the building is already recognized by state and federal law, no project related impacts are foreseen for the structure.

The Post Office, Customhouse, and Courthouse Building (King David Kalākaua Building), Dillingham Transportation Building, and U.S. Immigration Office are properties with NRHP and State Register of Historic Places status and are adjacent to the project area. These properties have not been identified in previous CIA. However, no potential impacts caused by the project are foreseen.

6.2 Cultural Learning Facilities

A total of seven cultural learning facilities were identified within the Kaka‘ako TOD Overlay project area, consisting of the African American Diversity Cultural Center of Hawai‘i (AADCCH), Diverse Art Center, Hawai‘i Children’s Center, Maritime Museum, and Nā Mea/Native Books Hawai‘i. Each learning facility is a unique cultural resource for the community of Kaka‘ako and the island-wide community.

The African American Diversity Cultural Center of Hawai‘i (AADCCH) is a one-of-a-kind repository of archival documents, researched data, and artifacts pertaining to Africans and African Americans in Hawai‘i’s History. In addition, the facility is a location in which knowledgeable individuals can be accessed for guidance on the subject. The AADCCH is a Non-Profit that currently rents a humble office space for its growing collection, which leaves little room for visitors. While the AADCCH hopes to expand, the rising cost of rent in Kaka‘ako may be a huge obstacle in meeting their goal. Therefore, potential impacts from the project are increased lease fees. It is recommended that the topic of impacts to contemporary cultural resources, such as AADCCH, be addressed in upcoming community discussions regarding the Kaka‘ako TOD Overlay project. One mitigation measure may be to encourage leasors to offer adjusted rent spaces for this and comparable institutions.

Similarly, the Home of the Brave Tour and museum is an irreplaceable cultural learning facility. This World War II repository has an extensive collection of artifacts and replicas as well as oral histories of the amazing personal experiences relayed to the tour operators by the WWII veterans themselves. As we are losing our WWII veterans at an increasing rate due to “old age,” Home of the Brave Tour and museum is a vital cultural resource. Unlike other cultural learning facilities, this facility is dependent on the structure that it is currently housed, due to twenty years of painstaking modifications to create and incorporate interpretive displays in to the structure. Impacts to the cultural resource would be loss of the current space it is housed in. Community discussions for the Kaka‘ako TOD Overlay should involve the topic of impacts to contemporary cultural resources, such as the Home of the Brave Tour and museum, which could bolster support for this valuable institution. It is recommended that project relateed developments work around the structure and leasors be encouraged to offer adjusted rent spaces for this and comparable institutions.

Diverse Art Center and The Refuge, run by 808 Urban, are unique urban and street art cultural learning facilities that services the youth and young adults of Kaka‘ako and surrounding areas. These organizations are also Non-Profits that provide a safe space for creating art and access to

artists for mentorship. The major foreseeable impact to these institutions is loss of leased space in Kakaʻako due to increased rent from project related developments. The recommendation is to address the topic of impacts to cultural resources like these during Kakaʻako TOD Overlay community discussions to increase awareness of resources of this nature as important features of Kakaʻako's cultural landscape. One mitigation measure may be to encourage leasors to offer adjusted rent spaces for these and similar institutions.

The Hawaiʻi Children's Center is also an important cultural resource that helps inner city children and children island-wide to interact with other children while interfacing with educational exhibits. Unlike school, this resource is not regimented and allows the parents to participate in the child's experience. One impact would be loss of leased space due to increased rents. Again, the recommended action is to incorporate the subject of contemporary cultural resources in upcoming Kakaʻako TOD Overlay community discussions, which could bolster support for this valuable institution.

The Maritime Museum was an operable museum until recent years, closing in 2009. As the former museum is not planned to be re-opened in the near future, it is not possible to determine if it will be impacted by the proposed development.

Nā Mea/Native Books Hawaiʻi is another unique cultural resource in Kakaʻako that retails an array of Hawaiiana books and music, arts and crafts, and raw materials to create Traditional Hawaiian crafts. It also hosts free workshops and lectures almost daily in Hawaiian traditions, such as storytelling, music making, *hula*, *lei* making, quilting, etc. Access to *kūpuna* such as those who specialize in various traditional crafts and knowledge is rarely available otherwise. Thus, Nā Mea/Native Books Hawaiʻi should be recognized as a contemporary cultural resource. Potential impacts include increased rents that could force the institution out of Kakaʻako. However, population increases due to project related development might increase store visitation and revenue. One mitigative measure may be to encourage leasors to offer adjusted rent spaces for this and comparable institutions during Kakaʻako TOD Overlay community discussions.

6.3 Public Parks and Grounds

Seven public parks and grounds have been identified in or adjacent to the project area, including Kakaʻako Waterfront Park, Kewalo Basin Park, Kakaʻako Makai Gateway Park, Mother Waldron Park/Playground, Ala Moana Beach Park, Irwin Park, and Thomas Square. Kakaʻako Waterfront Park, Kewalo Basin Park, Kakaʻako Makai Gateway Park, and Mother Waldron Neighborhood Park are located in the Kakaʻako TOD Overlay project area. Ala Moana Beach Park, Irwin Park, and Thomas Square are adjacent to the project area. By design, public open space parks and grounds are cultural resources and vital elements to the community, especially in urban settings.

All identified parks have individual characteristics, providing a particular physical attribute suitable for various specialized activities. A host of activities and events occur at these parks randomly, daily, weekly, monthly, and annually, and range from casual, random visitations to grand events attracting participants from all corners of the island. The general consensus from

community consultations is that these spaces are irreplaceable and dear to the community. As mentioned by CPAC Secretary and Archivist, Michelle Matson, in an email communication,

community leaders and development planners should be mindful that the community deserves the following:

- maintaining and increasing open park space
- maintaining open public access to our established ocean recreational areas
- mitigating problems from adverse overcrowding and over-development impacts on cultural and recreational shoreline park uses
- addressing ocean water quality concerns from storm water runoffs, as such may adversely impact and endanger shoreline recreation uses
- establishing a critical ocean safety and lifeguard facility to ensure effective first-responder and emergency treatment of shoreline park water users

She maintains, "…with all of the above being needed and necessary to support the present public recreational population of Kakaʻako Makai, as well as recreational needs of the anticipated population increase of 45,000 additional residents in the Kakaʻako area. Notably, our existing parks are at capacity on weekends and during events, and the National Standard for urban recreational open space to ensure the public health and welfare is 2 to 21/2 acres per 1000 capita (45,000 = 90 acres minimum)…" (Matson 2013).

Therefore, it is recommended that any impacts, such as project related development of park space to accommodate any activity other than public recreation be avoided. Access must remain open to the public and parking should be permanent elements of these parks, especially during large-scale events, to ensure accessibility to those coming from outer communities.

6.4 Memorials and Commemorations

A total of four memorials and commemorations have been identified for the project area. These include the Ehime Maru Memorial, MADD Victims' Memorial, Nagasaki Peace Bell, and Florentino Das Commemorative Plaque. Each of these cultural resources provides a unique space to remember and honor cherished individuals, victims of tragic events, and/or history makers. All memorials and commemorations are located in the project area, save for the Nagasaki Peace Bell.

Each memorial and commemoration appears actively used or visited by the community and should therefore be preserved in place. Potential impacts would be the removal of these cultural resources or encroachment of objects or structures in the dedicated space around the memorial or commemoration feature. It is recommended that development avoid these spaces.

6.5 Religious and Spiritual Gathering Places

In total, four long-standing churches in or adjacent to the project area have been identified, including the First Chinese Church of Christ, Kawaiahaʻo Church, Ke Alaula Oka Malamalama (The Bright Morning Rays of the Church of Reasonable Service), and Makiki Christian Church.

Each church actively serves the community by providing a distinctive type of ceremonial and religious service, such as sermons in languages spoke in the respective community it represents. In addition, these intuitions are largely housed in Historic era structures that are eligible if not already listed in the NRHP and State Register of Historic Places. Impacts could be decreased access due to lack of parking. It is recommended that these properties be avoided in project related development.

6.6 Public Art Installation & Entertainment Centers

A total of four public art installation and entertainment centers were identified in this study, including POW! WOW!, Neal S. Blaisdell Concert and Exhibition Complex, FreshCafe & Loft in Space, and various vacant lots & thoroughfares. All of these cultural resources are located within the project area.

POW!WOW! is actually an annual weeklong event that showcases an array of large urban or street art murals installed throughout Kaka'ako. These murals are significant resources for the arts community as well as the general public who view these murals. The event also provides the opportunity for artists to interact and learn from other artists from around the globe. Potential impacts to this newer institution could be the loss of space for murals due to project related development. It is recommended that the topic of sanctioned public art, such as the art installed during the POW!WOW! events be addressed in upcoming Kaka'ako TOD Overlay community discussions to ascertain the importance of these cultural resources to the community.

The Neal S. Blaisdell Concert and Exhibition Complex is the main venue on O'ahu for large-scale performances and exhibitions. This irreplaceable resource has been the home of nurmerous cultural events throughout its history and will be eligible for NRHP and State Register of Historic Places status in the near future. Impacts may include reduced access due to project related development. It is advised that this important cultural resource be avoided by development that is not supportive of arts and entertainment.

The Fresh Cafe & Loft in Space has become an important venue for up-and-coming artists and aspiring artists of all genres. This space allows artists to collaborate, present art, sell arts and crafts, lecture, learn, and debate all aspects of contemporary art. This creative space/artist think tank could be impacted by raised rent and reduced parking availability due to project related developments. Introducing the topic of project related impacts to contemporary cultural resources is recommended during upcoming Kaka'ako TOD Overlay community discussions. One mitigation measure may be to encourage leasors to offer adjusted rent spaces for these and similar institutions.

In addition to formal or dedicated areas for cultural activities, there are several vacant lots and thoroughfares that are venues for regular cultural events, perhaps unique to Kaka'ako, such as Art & Flea, Eat the Street, Honolulu Night Market, Honolulu 5K and 1 Mile Keiki Run/Walk, King Kamehameha Floral Parade, Pow!Wow! Hawai'i, and Three Walls Music Festival. These events are not dependent on the particular space that they occur on – they simply need open venues. However, these events have become part of the charm and attraction to the area. The

main impact to these activities would be loss of space. Addressing the topic of contemporary cultural practices, such as the afore mentioned, as important facets of Kaka'ako's cultural landscape and how they might be impacted by the proposed action during upcoming community discussions is recommended.

APPENDIX A

Guidelines for Assessing Cultural Impacts
(Office of Environmental Quality Control 1997)
And
Text of Act 50
(State Legislature Hawai'i 2000)

Guidelines for Assessing Cultural Impacts

Adopted by the Environmental Council, State of Hawaii
November 19, 1997

1. INTRODUCTION

It is the policy of the State of Hawaii under Chapter 343, HRS, to alert decision makers, through the environmental assessment process, about significant environmental effects which may result from the implementation of certain actions. An environmental assessment of cultural impacts gathers information about cultural practices and cultural features that may be affected by actions subject to Chapter 343, and promotes responsible decision making.

Articles IX and XII of the State Constitution, other state laws, and the courts of the state require government agencies to promote and preserve cultural beliefs, practices, and resources of native Hawaiians and other ethnic groups. Chapter 343 also requires environmental assessment of cultural resources, in determining the significance of a proposed project.

The Environmental Council encourages preparers of environmental assessments and environmental impact statements to analyze the impact of a proposed action on cultural practices and features associated with the project area. The Council provides the following methodology and content protocol as guidance for any assessment of a project that may significantly affect cultural resources.

Background

Prior to the arrival of westerners and the ideas of private land ownership, Hawaiians freely accessed and gathered resources of the land and seas to fulfill their community responsibilities. During the Mahele of 1848, large tracts of land were divided and control was given to private individuals. When King Kamehameha the III was forced to set up this new system of land ownership, he reserved the right of access to privately owned lands for Native Hawaiian ahupua'a tenants. However, with the later emergence of the western concept of land ownership, many Hawaiians were denied access to previously available traditional resources.

In 1978, the Hawaii constitution was amended to protect and preserve traditional and customary rights of Native Hawaiians. Then in 1995 the Hawaii Supreme Court confirmed that Native Hawaiians have rights to access undeveloped and under-developed private lands. Recently, state lawmakers clarified that government agencies and private developers must assess the impacts of their development on the traditional practices of Native Hawaiians as well as the cultural resources of all people of Hawaii. These Hawaii laws, and the National Historic Preservation Act, clearly mandate federal agencies in Hawaii, including the military, to evaluate the impacts of their actions on traditional practices and cultural resources.

If you own or control undeveloped or under-developed lands in Hawaii, here are some hints as to whether traditional practices are occurring or may have occurred on your lands. If there is a trail on your property, that may be an indication of traditional practices or customary usage. Other clues include streams, caves and native plants. Another important point to remember is that, although traditional practices may have been interrupted for many years, these customary practices cannot be denied in the future.

These traditional practices of Native Hawaiians were primarily for subsistence, medicinal, religious, and cultural purposes. Examples of traditional subsistence practices include fishing, picking opihi and collecting limu or seaweed. The collection of herbs to cure the sick is an example of a traditional medicinal practice. The underlying purpose for conducting these traditional practices is to fulfill one's community responsibilities, such as feeding people or healing the sick.

As it is the responsibility of Native Hawaiians to conduct these traditional practices, government agencies and private developers also have a responsibility to follow the law and assess the impacts of their actions on traditional and cultural resources.

The State Environmental Council has prepared guidelines for assessing cultural resources and has compiled a directory of cultural consultants who can conduct such studies. The State Historic Preservation Division has drafted guidelines on how to conduct ethnographic inventory surveys. And the Office of Planning has recently completed a case study on traditional gathering rights on Kaua'i.

The most important element of preparing Cultural Impact Assessments is consulting with community groups, especially with expert and responsible cultural practioners within the ahupua'a of the project site. Conducting the appropriate documentary research should then follow the interviews with the experts. Documentary research should include analysis of mahele and land records and review of transcripts of previous ethnographic interviews. Once all the information has been collected, and verified by the community experts, the assessment can then be used to protect and preserve these valuable traditional practices.

Native Hawaiians performed these traditional and customary practices out of a sense of responsibility: to feed their families, cure the sick, nurture the land, and honor their ancestors. As stewards of this sacred land, we too have a responsibility to preserve, protect and restore these cultural resources for future generations.

TEXT OF ACT 50, SLH 2000

A BILL FOR AN ACT RELATING TO ENVIRONMENTAL IMPACT STATEMENTS

UNOFFICIAL VERSION

HOUSE OF REPRESENTATIVES H.B. NO. 2895 H.D.1

TWENTIETH LEGISLATURE, 2000

STATE OF HAWAII

A BILL FOR AN ACT

RELATING TO ENVIRONMENTAL IMPACT STATEMENTS.

BE IT ENACTED BY THE LEGISLATURE OF THE STATE OF HAWAII:

SECTION 1. The legislature finds that there is a need to clarify that the preparation of environmental assessments or environmental impact statements should identify and address effects on Hawai'i's culture, and traditional and customary rights.

The legislature also finds that native Hawaiian culture plays a vital role in preserving and advancing the unique quality of life and the "aloha spirit' in Hawaii. Articles IX and XII of the state constitution, other state laws, and the courts of the State impose on government agencies a duty to promote and protect cultural beliefs, practices, and resources of native Hawaiians as well as other ethnic groups.

Moreover, the past failure to require native Hawaiian cultural impact assessments has resulted in the loss and destruction of many important cultural resources and has interfered with the exercise of native Hawaiian culture. The legislature further finds that due consideration of the effects of human activities on native Hawaiian culture and the exercise thereof is necessary to ensure the continued existence, development, and exercise of native Hawaiian culture.

The purpose of this Act is to: (1) Require that environmental impact statements include the disclosure of the effects of a proposed action on the cultural practices of the community and State; and (2) Amend the definition of "significant effect" to include adverse effects on cultural practices.

SECTION 2. Section 343-2, Hawai`i Revised Statutes, is amended by amending the definitions of "environmental impact statement' or "statement" and "significant effect", to read as follows:

"'Environmental impact statement" or "statement" means an informational document prepared in compliance with the rules adopted under section 343-6 and which discloses the environmental effects of a proposed action, effects of a proposed action on the economic [and] welfare, social welfare, and cultural practices of the community and State, effects of the economic activities arising out of the proposed action, measures proposed to minimize adverse effects, and alternatives to the action and their environmental effects.

The initial statement filed for public review shall be referred to as the draft statement and shall be distinguished from the final statement which is the document that has incorporated the public's comments and the responses to those comments. The final statement is the document that shall be evaluated for acceptability by the respective accepting authority.

"Significant effect" means the sum of effects on the quality of the environment, including actions that irrevocably commit a natural resource, curtail the range of beneficial uses of the environment, are contrary to the State's environmental policies or long-term environmental goals as established by law, or adversely affect the economic [or] welfare, social welfare[,], or cultural practices of the community and State."

SECTION 3. Statutory material to be repealed is bracketed. New statutory material is underscored.

SECTION 4. This Act shall take effect upon its approval.

Approved by the Governor as Act 50 on April 26, 2000

2. CULTURAL IMPACT ASSESSMENT METHODOLOGY

Cultural impacts differ from other types of impacts assessed in environmental assessments or environmental impact statements. A cultural impact assessment includes information relating to the practices and beliefs of a particular cultural or ethnic group or groups.

Such information may be obtained through scoping, community meetings, ethnographic interviews and oral histories. Information provided by knowledgeable informants, including traditional cultural practitioners, can be applied to the analysis of cultural impacts in conjunction with information concerning cultural practices and features obtained through consultation and from documentary research.

In scoping the cultural portion of an environmental assessment, the geographical extent of the inquiry should, in most instances, be greater than the area over which the proposed action will take place. This is to ensure that cultural practices which may not occur within the boundaries of the project area, but which may nonetheless be affected, are included in the assessment. Thus, for example, a proposed action that may not physically alter gathering practices, but may affect access to gathering areas would be included in the assessment. An ahupua'a is usually the appropriate geographical unit to begin an assessment of cultural impacts of a proposed action, particularly if it includes all of the types of cultural practices associated with the project area. In some cases, cultural practices are likely to extend beyond the ahupua'a and the geographical extent of the study area should take into account those cultural practices.

The historical period studied in a cultural impact assessment should commence with the initial presence in the area of the particular group whose cultural practices and features are being assessed. The types of cultural practices and beliefs subject to assessment may include subsistence, commercial, residential, agricultural, access-related, recreational, and religious and spiritual customs.

The types of cultural resources subject to assessment may include traditional cultural properties or other types of historic sites, both man made and natural, including submerged cultural resources, which support such cultural practices and beliefs.

The Environmental Council recommends that preparers of assessments analyzing cultural impacts adopt the following protocol:

1. identify and consult with individuals and organizations with expertise concerning the types of cultural resources, practices and beliefs found within the broad geographical area, e.g., district or ahupua`a;
2. identify and consult with individuals and organizations with knowledge of the area potentially affected by the proposed action;
3. receive information from or conduct ethnographic interviews and oral histories with persons having knowledge of the potentially affected area;
4. conduct ethnographic, historical, anthropological, sociological, and other culturally related documentary research;
5. identify and describe the cultural resources, practices and beliefs located within the potentially affected area; and
6. assess the impact of the proposed action, alternatives to the proposed action, and mitigation measures, on the cultural resources, practices and beliefs identified.

Interviews and oral histories with knowledgeable individuals may be recorded, if consent is given, and field visits by preparers accompanied by informants are encouraged. Persons interviewed should be afforded an opportunity to review the record of the interview, and consent to publish the record should be obtained whenever possible. For example, the precise location of human burials are likely to be withheld from a cultural impact assessment, but it is important that the document identify the impact a project would have on the burials. At times an informant may provide information only on the condition that it remain in confidence. The wishes of the informant should be respected.

Primary source materials reviewed and analyzed may include, as appropriate: Mahele, land court, census and tax records, including testimonies; vital statistics records; family histories and genealogies; previously published or recorded ethnographic interviews and oral histories; community studies, old maps and photographs; and other archival documents, including correspondence, newspaper or almanac articles, and visitor journals. Secondary source materials such as historical, sociological, and anthropological texts, manuscripts, and similar materials, published and unpublished, should also be consulted. Other materials which should be examined include prior land use proposals, decisions, and rulings which pertain to the study area.

3. CULTURAL IMPACT ASSESSMENT CONTENTS

In addition to the content requirements for environmental assessments and environmental impact statements, which are set out in HAR §§ 11-200-10 and 16 through 18, the portion of the assessment concerning cultural impacts should address, but not necessarily be limited to, the following matters:

1. A discussion of the methods applied and results of consultation with individuals and organizations identified by the preparer as being familiar with cultural practices and features associated with the project area, including any constraints or limitations which might have affected the quality of the information obtained.
2. A description of methods adopted by the preparer to identify, locate, and select the persons interviewed, including a discussion of the level of effort undertaken.
3. Ethnographic and oral history interview procedures, including the circumstances under which the interviews were conducted, and any constraints or limitations which might have affected the quality of the information obtained.
4. Biographical information concerning the individuals and organizations consulted, their particular expertise, and their historical and genealogical relationship to the project area, as well as information concerning the persons submitting information or interviewed, their particular knowledge and cultural expertise, if any, and their historical and genealogical relationship to the project area.
5. A discussion concerning historical and cultural source materials consulted, the institutions and repositories searched, and the level of effort undertaken. This discussion should include, if appropriate, the particular perspective of the authors, any opposing views, and any other relevant constraints, limitations or biases.
6. A discussion concerning the cultural resources, practices and beliefs identified, and, for resources and practices, their location within the broad geographical area in which the proposed action is located, as well as their direct or indirect significance or connection to the project site.
7. A discussion concerning the nature of the cultural practices and beliefs, and the significance of the cultural resources within the project area, affected directly or indirectly by the proposed project.

8. An explanation of confidential information that has been withheld from public disclosure in the assessment.
9. A discussion concerning any conflicting information in regard to identified cultural resources, practices and beliefs.
10. An analysis of the potential effect of any proposed physical alteration on cultural resources, practices or beliefs; the potential of the proposed action to isolate cultural resources, practices or beliefs from their setting; and the potential of the proposed action to introduce elements which may alter the setting in which cultural practices take place.
11. A bibliography of references, and attached records of interviews which were allowed to be disclosed.

The inclusion of this information will help make environmental assessments and environmental impact statements complete and meet the requirements of Chapter 343, HRS. If you have any questions, please call 586-4185.

APPENDIX B

Selected data from NRCS Customized Soil Reports for Contiguous and Non-contiguous
Kaka'ako TOD Overlay Project Area
(Full reports available upon request)

Map Unit Legend

Island of Oahu, Hawaii (HI990)			
Map Unit Symbol	Map Unit Name	Acres in AOI	Percent of AOI
EmA	Ewa silty clay loam, moderately shallow, 0 to 2 percent slopes	24.9	4.1%
FL	Fill land, mixed	469.7	80.8%
MkA	Makiki clay loam, 0 to 2 percent slopes	144.2	23.9%
Subtotals for Soil Survey Area		578.8	94.3%
Totals for Area of Interest		613.6	100.0%

Map Unit Descriptions

The map units delineated on the detailed soil maps in a soil survey represent the soils or miscellaneous areas in the survey area. The map unit descriptions, along with the maps, can be used to determine the composition and properties of a unit.

A map unit delineation on a soil map represents an area dominated by one or more major kinds of soil or miscellaneous areas. A map unit is identified and named according to the taxonomic classification of the dominant soils. Within a taxonomic class there are precisely defined limits for the properties of the soils. On the landscape, however, the soils are natural phenomena, and they have the characteristic variability of all natural phenomena. Thus, the range of some observed properties may extend beyond the limits defined for a taxonomic class. Areas of soils of a single taxonomic class rarely, if ever, can be mapped without including areas of other taxonomic classes. Consequently, every map unit is made up of the soils or miscellaneous areas for which it is named and some minor components that belong to taxonomic classes other than those of the major soils.

Most minor soils have properties similar to those of the dominant soil or soils in the map unit, and thus they do not affect use and management. These are called noncontrasting, or similar, components. They may or may not be mentioned in a particular map unit description. Other minor components, however, have properties and behavioral characteristics divergent enough to affect use or to require different management. These are called contrasting, or dissimilar, components. They generally are in small areas and could not be mapped separately because of the scale used. Some small areas of strongly contrasting soils or miscellaneous areas are identified by a special symbol on the maps. If included in the database for a given area, the contrasting minor components are identified in the map unit descriptions along with some characteristics of each. A few areas of minor components may not have been observed, and consequently they are not mentioned in the descriptions, especially where the pattern was so complex that it was impractical to make enough observations to identify all the soils and miscellaneous areas on the landscape.

The presence of minor components in a map unit in no way diminishes the usefulness or accuracy of the data. The objective of mapping is not to delineate pure taxonomic classes but rather to separate the landscape into landforms or landform segments that

have similar use and management requirements. The delineation of such segments on the map provides sufficient information for the development of resource plans. If intensive use of small areas is planned, however, onsite investigation is needed to define and locate the soils and miscellaneous areas.

An identifying symbol precedes the map unit name in the map unit descriptions. Each description includes general facts about the unit and gives important soil properties and qualities.

Soils that have profiles that are almost alike make up a *soil series*. Except for differences in texture of the surface layer, all the soils of a series have major horizons that are similar in composition, thickness, and arrangement.

Soils of one series can differ in texture of the surface layer, slope, stoniness, salinity, degree of erosion, and other characteristics that affect their use. On the basis of such differences, a soil series is divided into *soil phases*. Most of the areas shown on the detailed soil maps are phases of soil series. The name of a soil phase commonly indicates a feature that affects use or management. For example, Alpha silt loam, 0 to 2 percent slopes, is a phase of the Alpha series.

Some map units are made up of two or more major soils or miscellaneous areas. These map units are complexes, associations, or undifferentiated groups.

A *complex* consists of two or more soils or miscellaneous areas in such an intricate pattern or in such small areas that they cannot be shown separately on the maps. The pattern and proportion of the soils or miscellaneous areas are somewhat similar in all areas. Alpha-Beta complex, 0 to 6 percent slopes, is an example.

An *association* is made up of two or more geographically associated soils or miscellaneous areas that are shown as one unit on the maps. Because of present or anticipated uses of the map units in the survey area, it was not considered practical or necessary to map the soils or miscellaneous areas separately. The pattern and relative proportion of the soils or miscellaneous areas are somewhat similar. Alpha-Beta association, 0 to 2 percent slopes, is an example.

An *undifferentiated group* is made up of two or more soils or miscellaneous areas that could be mapped individually but are mapped as one unit because similar interpretations can be made for use and management. The pattern and proportion of the soils or miscellaneous areas in a mapped area are not uniform. An area can be made up of only one of the major soils or miscellaneous areas, or it can be made up of all of them. Alpha and Beta soils, 0 to 2 percent slopes, is an example.

Some surveys include *miscellaneous areas*. Such areas have little or no soil material and support little or no vegetation. Rock outcrop is an example.

Island of Oahu, Hawaii

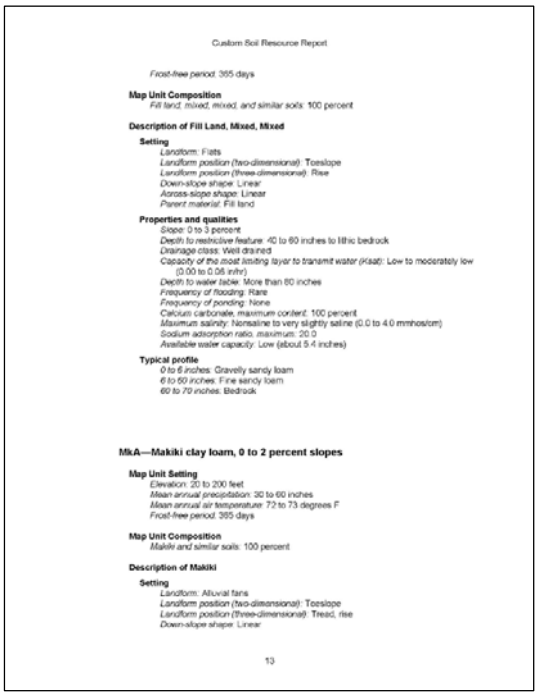
EmA—Ewa silty clay loam, moderately shallow, 0 to 2 percent slopes

Map Unit Setting
Elevation: 0 to 150 feet
Mean annual precipitation: 15 to 30 inches
Mean annual air temperature: 73 to 75 degrees F
Frost-free period: 365 days

Map Unit Composition
Ewa and similar soils: 100 percent

Description of Ewa

Setting
Landform position (two-dimensional): Footslope
Landform position (three-dimensional): Tread
Down-slope shape: Convex
Across-slope shape: Linear



Properties and qualities
Slope: 0 to 2 percent
Depth to restrictive feature: 20 to 40 inches to paralithic bedrock
Drainage class: Well drained
Capacity of the most limiting layer to transmit water (Ksat): Moderately low to high (0.14 to 1.98 in/hr)
Depth to water table: More than 80 inches
Frequency of flooding: None
Frequency of ponding: None
Calcium carbonate, maximum content: 99 percent
Sodium adsorption ratio, maximum: 4.0
Available water capacity: Low (about 3.6 inches)

Interpretive groups
Farmland classification: Prime farmland if irrigated
Land capability classification (irrigated): 2s
Land capability (nonirrigated): 4s
Hydrologic Soil Group: B

Typical profile
0 to 8 inches: Silty clay loam
8 to 29 inches: Silty clay loam
29 to 39 inches: Bedrock

FL—Fill land, mixed

Map Unit Setting
Elevation: 0 to 500 feet
Mean annual precipitation: 15 to 60 inches
Mean annual air temperature: 73 to 75 degrees F

Custom Soil Resource Report

Frost-free period: 365 days

Map Unit Composition
Fill land, mixed, mixed, and similar soils: 100 percent

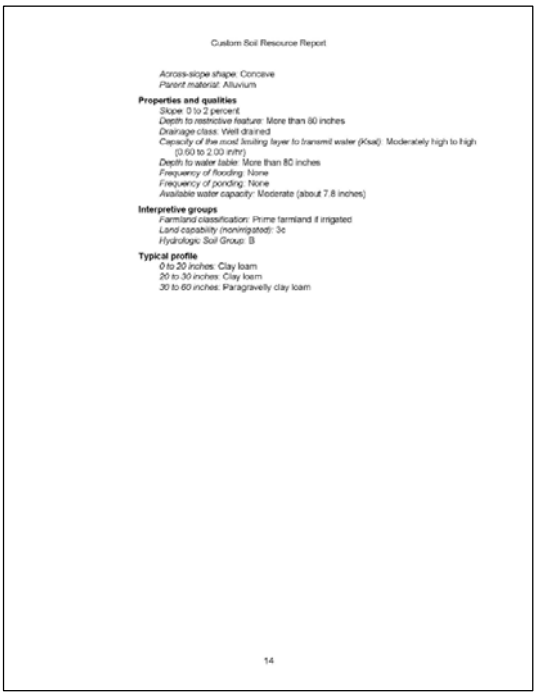
Description of Fill Land, Mixed, Mixed

Setting
Landform: Flats
Landform position (two-dimensional): Toeslope
Landform position (three-dimensional): Rise
Down-slope shape: Linear
Across-slope shape: Linear
Parent material: Fill land

Properties and qualities
Slope: 0 to 3 percent
Depth to restrictive feature: 40 to 60 inches to lithic bedrock
Drainage class: Well drained
Capacity of the most limiting layer to transmit water (Ksat): Low to moderately low (0.00 to 0.06 in/hr)
Depth to water table: More than 80 inches
Frequency of flooding: Rare
Frequency of ponding: None
Calcium carbonate, maximum content: 100 percent
Maximum salinity: Nonsaline to very slightly saline (0.0 to 4.0 mmhos/cm)
Sodium adsorption ratio, maximum: 20.0
Available water capacity: Low (about 5.4 inches)

Typical profile
0 to 6 inches: Gravelly sandy loam
6 to 50 inches: Fine sandy loam
60 to 70 inches: Bedrock

MkA—Makiki clay loam, 0 to 2 percent slopes



Map Unit Setting
Elevation: 20 to 200 feet
Mean annual precipitation: 30 to 60 inches
Mean annual air temperature: 72 to 73 degrees F
Frost-free period: 365 days

Map Unit Composition
Makiki and similar soils: 100 percent

Description of Makiki

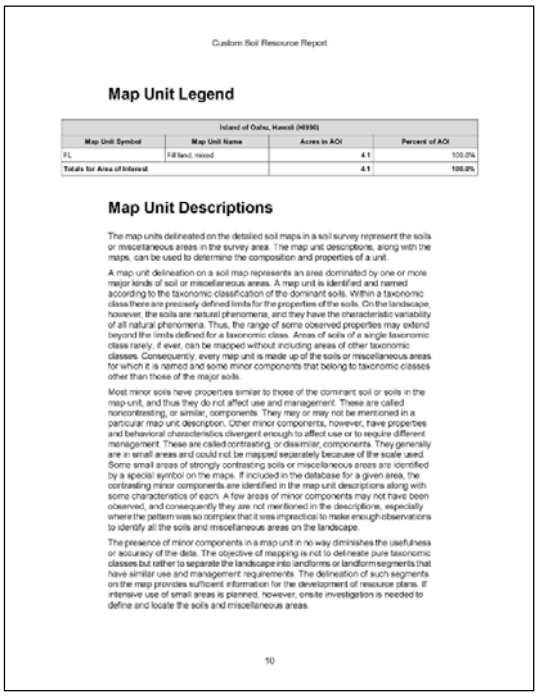
Setting
Landform: Alluvial fans
Landform position (two-dimensional): Toeslope
Landform position (three-dimensional): Tread, rise
Down-slope shape: Linear

13

Custom Soil Resource Report

Across-slope shape: Concave
Parent material: Alluvium

Properties and qualities
Slope: 0 to 2 percent
Depth to restrictive feature: More than 80 inches
Drainage class: Well drained
Capacity of the most limiting layer to transmit water (Ksat): Moderately high to high (0.60 to 2.00 in/hr)
Depth to water table: More than 80 inches
Frequency of flooding: None
Frequency of ponding: None
Available water capacity: Moderate (about 7.8 inches)



Interpretive groups
Farmland classification: Prime farmland if irrigated
Land capability (nonirrigated): 3c
Hydrologic Soil Group: B

Typical profile
0 to 20 inches: Clay loam
20 to 30 inches: Clay loam
30 to 60 inches: Paragravelly clay loam

Contact List/Communication Log

Kakaʻako Transit Oriented Development Supplemental Cultural Impact Assessment - Cultural Informants				
Name	**Affiliation/Association**	**Priority**	**Contact Log**	**Participation**
Abinales, Patricio	UH Manoa, School of Pacific and Asian Studies, Re: Florentino Das Memorial	Medium	7/25/13 sent email request; 7/25/13 Mr. Abinales replies via email, refers me to COVO	**Refers COVO**
Ala Moana Center	In project area	High	8/6/13 send request email to Ala Moana Center website; no response	**None**
Aloha Festivals	Several events in and adjacent to project area	High	7/29/13 sent request email to Aloha Festivals website; 8/13/13 received response from JoAnn Morimoto referring me to Toni Lee (forwards email to Ms. Lee); 8/18/13 Ms. Lee responds via email and agrees to participate; 8/20/13 call Ms. Lee to set up interview; says she would like to do online questionnaire; no record of participation online	**Unable to participate**
Ayau, Edward H.	Interviewed, in Vogeler et al. 2010	Medium	8/5/13 sent request letter	**None**
Ayers, Patrick	German Shepherd Dog Club of Hawaii, president (use Thomas Square Park for shows)	Low	8/13/13-8/15/13 several email communications between Mr. Ayers and myself; 8/13/13 participates in online questionnaire, but withdraws comments via email 8/13/13	**Online Questionnaire**
Bandack, Fred	Hawaiʻi Gateball Association (weekly gateball & groundgolf games @ Ala Moana Park)	Medium	8/12/13 called & spoke with Fred, he said to meet him on Sunday morning for interview; 8/17/13 waited at Ala Moana Park for Fred and he had last minute cancellation; 8/19/13 called Fred and he agreed to participate in online questionnaire	**Unable to participate**
Bishop Museum	Maritime Museum and *Falls of Clyde* management	High	7/25/13: sent request letter; 8/19/13 called, spoke with Carole (Executive offices receptionist) & she asked me to email copy of letter; 8/26/13 got response from Noa Dettweiler with information on the Hawaii Maritime Museum and Falls of Clyde; 8/26/13 responded via email	**Emailed status of properties**
Bowen, Margaret	Aloha State Sporting Dog Assn. (Re: events at Thomas Square Park)	Medium	8/13/13 send request email; 8/13/13 Ms. Bowen responds via email; 8/13/13 Ms. Bowen provides more info via email; 8/13/13 thank Ms. Bowen via email	**Shared info via email**
Colmenares, Dr. Serafin	Congress of Visayan Organizations (COVO), Re: Florentino Das Memorial	High	F. Magdelena referred me to Dr. Colmenares; 7/29/13 sent Dr. Colmenares request email;	**Online Questionnaire**
Crabbe, Kamanaʻopono	Office of Hawaiian Affairs, CEO	High	7/22/13: sent letter to Mr. Crabbe;	**Responds via letter**
Davis, Jeff	Eat the Street and Honolulu Night Market organizer	High	7/24/13: sent email request to Jeff; 7/25/13 Jeff replied and sent request to person in charge with media requests	**Unable to participate**
Dawson, Beadie K.	Cultural practitioner& raised in Kakaʻako; Interviewee (Maly et al. 2013)	Medium	8/7/13 sent letter asking if she was interested in further CIA participation	**None**
Department of Land& Natural Resources	Oversees state parks in Kakaʻako	High	7/23/13 sent letter to both offices to request information	**None**
Dettweiler, Kahikino Noa	Bishop Museum, General Counsel	Low	8/26/13 got response from Noa Dettweiler with information on the Hawaii Maritime Museum and Falls of Clyde; 8/26/13 responded via email	**Information via email**
Dreith, Madeleine	US Tennis Association/ Hawaiʻi Pacific Section, Directory of Community Tennis (Re: Ala Moana Park Tennis Courts)	Low	8/13/13 emailed USTA (3 separate admin.) requesting participation; 8/18/13 submits online questionnaire	**Online questionnaire**
Guttman, Delores	African American Diversity Cultural Center Hawai'i located in Kakaʻako	High	8/6/13 called AADCCH and left request message; 8/9/13 Ms. Guttman calls back, leaves message; 8/9/13 return Ms. Guttman's call, speak with Ms. Guttman, explaining project and settle on a date to interview; 8/22/13 interview Ms. Guttman at AADCCH headquarters	**Interview**

Kaka'ako Transit Oriented Development Supplemental Cultural Impact Assessment - Cultural Informants				
Name	**Affiliation/Association**	**Priority**	**Contact Log**	**Participation**
Gora, Francine	Interviewed, in Elison (2013)	Medium	8/7/13 sent letter asking if she was interested in further CIA participation	**None**
Grace Bible Church Honolulu	In project area	Low	7/23/13: sent request letter	**None**
Fang, Wei	Owner - R&D curated bookstore, coffee shop and workspace in Kaka'ako	Medium	7/24/13 sent email request to "R/D curated bookstore, coffee shop and workspace", 7/25/13 Ms. Fang replies to email requesting more info, reply same day; 7/26/13 Ms. Fang agrees to meet; 8/9/13 offer to meet later in week; 8/12/13 Ms. Fang suggests Thurs 8/15; 8/13/13 set date; 8/15/13 interview at 1pm w/ Ms. Fang; through interview found out R/D would be closing its doors and not reopening due to loss of affordable lease space	**Interview, but found that the resource will not continue into the next year**
Felly, Taryn	General Growth Properties, Kaka'ako	Low	7/25/13 sent request email	**None**
First Chinese Church of Christ	Location adjacent to project area	Medium	7/23/13: sent request letter	**None**
Hanapa'a Fishing	Fishing & diving tournaments in waters all over the island	Medium	7/24/13: sent request letter	**None**
Haole, Bill	Kawaiaha'o Church; Interviewed, in Elison & McElroy (2011)		8/7/13 sent letter asking if she was interested in further CIA participation ; 8/26/13 spoke with Bill on phone; said he would be in contact; no response	**Unable to participate**
Hawai'i Children's Discovery Center	111 Ohe Street Honolulu, Hawaii 96813 Phone: (808) 524-KIDS (524-5437) Fax: (808) 524-5400 info@discoverycenterhawaii.org	High	7/25/13 sent email request	**None**
Hawaii LGBT Legacy Foundation	Annual Pride Parade begins at Ala Moana Park and Pride Fair takes place at Ala Moana Park	Medium	8/5/13: sent request letter	**None**
Hawai'i Philadelphia Mission	In project area	Low	7/23/13: sent request letter	**None**
Hawai'i State Library	Location adjacent to project area	Medium	7/25/13: sent request letter	**None**
Hawaiian Civic Club of Honolulu	Location adjacent to project area	Medium	7/23/13: sent request letter	**None**
Hawaiian Mission Houses	In project area	High	7/25/13: sent request letter	**None**
Hawkins, Edward	Japan-America Society of Hawaii & Ehime Maru Memorial Association, President	High	7/25/13: sent request email to admindir@jashawaii.org; 7/25/13 response from Ed Hawkins, Pres. Japan-America Society of HI (several email exchanges); 7/29/13 called Mr. Hawkins and left message; 7/29/13 Mr. Hawkins called and asked to speak later today; 8/5/13 after several email exchanges, Mr. Hawkins submits online questionnaire, I email him to notify it was a success;	**Online Questionnaire**
His Highest Praise Honolulu	In project area	Low	7/23/13: sent request letter	**None**
Ho, Roy	Nā Lei Aloha Foundation, Executive Director (Re: Lantern Floating Ceremony @ Ala Moana Park)	Medium	8/14/13 call & leave message on machine as well as email Mr. Ho;	**Interview**
Holy Theotokos of Iveron Russian Orthodox Church	In project area	Low	7/23/13: sent request letter	**None**

Kaka'ako Transit Oriented Development Supplemental Cultural Impact Assessment - Cultural Informants				
Name	**Affiliation/Association**	**Priority**	**Contact Log**	**Participation**
Inouye, Christine	Obedience Training Club of Hawai`i, President (Re: activities at Thomas Square Park)	Medium	8/14/13 emailed me to agree to participate in online questionnaire; no record of questionnaire submittal	**Unable to participate**
Iwai, Thomas	Friends of Kewalos	High	8/15/13 interview Mr. Iwai with Ron Iwami at Kewalo Basin	**Interview**
Iwami, Ron	Friends of Kewalos	High	7/31/13 Bob Richmond forwarded my request email to Ron; 8/5/13 Ron responds to forwarded email to agree to participate; 8/5/13 I respond to Ron's email and provide him with a link to view the online questionnaire to see what type of information I'm looking for; 8/9/13 email Ron to set a date for interview; 8/15/13 perform joint interview with Ron and Tom Iwai at Kewalo Basin Park	**Interview**
Joyner, Marsha	Martin Luther King, Jr. Holiday Coalition (Re: Nagasaki Peace Bell Ringing ceremony on Honolulu Hale grounds)	Medium	7/29/13 sent email request; 7/29/13 M. Joyner responds to email request, agrees to participate in online questionnaire and sends pdf of information about the Nagasaki Peace Bell; no questionnaire response	**Sent info via email**
Kaanapu, Katie	Ward Centers, The Howard Hughes Corporation, Senior Marketing Manager (Re: Discover Kaka'ako)	Medium	8/12/13 was forwarded email request by Reed Tamashiro; 8/13/13 replied to email and agreed to fill out online questionnaire (did not fill out)	**Unable to participate**
Kaka'ako Christian Fellowship	Location adjacent to project area	Low	7/23/13: sent request letter	**None**
Kaleikini, Paulette Ka`anohi	Cultural practitioner& raised in Kaka'ako; Interviewee (Spear et al. 2008)	High	8/7/13 sent letter asking if she was interested in further CIA participation	**Did not wish to participate**
Kamai, May Kalehua	Cultural practitioner& raised in Kaka'ako; Interviewee (Elison & McElroy 2011)	High	8/8/13 called & left message	**None**
Kang, Jundong (sp.?)	Hawaii Jokgu Assn., President (Re: activities at Mother Waldron Park)	Medium	8/14/13 received email from info@jokguusa.com referring Mr. Kang; 8/19/13 called Mr. Kang & set a date for Sunday 3pm at Mother Waldron Park	**Unable to participate**
Kapanui, Lopaka	Cultural practitioner& raised in Kaka'ako; Interviewee (Elison & McElroy 2011)		8/8/13 called & left message; he called back and spoke with me, said I could use testimony in Elison & McElroy 2011, asked to send him link to online questionnaire; no record of participation	**Says to use info from previous CIA**
Kapua, Charles	Cultural practitioner& raised in Kaka'ako; Interviewee (Spearing et al. 2008; Vogeler et al. 2010)	High	8/7/13 sent request letter	**None**
Kasparovich, Cass K.	C & C of Honolulu DPR, Sheridan Community Park, Recreation Director	Medium	8/6/13 sent email request; 8/6/13 Ms. Kasparovitch responds to email and agrees to participate; 8/6/13 send pdf of questionnaire	**Sent information via email**
Kawaiaha'o Church	In project area	High	7/23/13: sent request letter	**None**
Ke Alaula Oka Malamalama	In project area	High	7/23/13: sent request letter	**None**
Keohokalole, Adrian Kealoha	Cultural informant in Spearing et al. (2008) and Maly et al. (2013)	Medium	8/7/13 sent request letter	**None**
Kululoio, Manuel M.	Interviewed, in Spearing et al. (2008) & Elison (2013)	High	8/7/13 sent request letter	**None**
Lawai'a Magazine	Fishing articles island wide	Low	7/24/13: sent request letter	**None**
Lee, Antoinette "Toni"	Aloha Festivals, Parade Chair (Re: parades occurring in or near Kaka'ako)	High	7/29/13 sent email request; 8/18/13 agrees to participate; no record of online participation	**Unable to participate**

Kaka'ako Transit Oriented Development Supplemental Cultural Impact Assessment - Cultural Informants				
Name	**Affiliation/Association**	**Priority**	**Contact Log**	**Participation**
Lee, Michael Kumukauoha	Interviewed, in Elison (2013)	High	8/7/13 sent request letter; 9/5/13 Mr. Lee responds via email and provides a phone number to call for interview set up; call provided number, but number is wrong; 9/16/13 email Mr. Lee to inform him that the number did not work; 10/21/13; email Mr. Lee again to offer chance to participate in online questionnaire; 11/5/13 receive email from Mr. Lee stating I can use information given in the Mother Waldron EIS (HART?); 11/5/13 respond via email to thank Mr. Lee	**Refers to previous cultural studies for general area**
Lee, Zachary	Department of Parks and Recreation, West Honolulu Recreation Supervisor	High	7/29/13 Mr. Lee returns call placed with Department of Parks and Recreation, 8/6/13 sends email with contact info for Steve Min, park manager for Ala Moana Regional Park/Mother Waldron Neighborhood Park	**Refers Steven Min and Cass Kasprovitch**
Lyovin, Father Anatole & Emyko Lyovin	Holy Theotokos of Iveron Russian Orthodox Church, Located on Queen St. in Kaka'ako	Medium	7/25/13 sent request letter; 8/19/13 called & spoke with Father Lyovin's wife, Emyko, who had no knowledge of letter sent, but would speak with her husband about an informal interview (took down my contact info); 8/21/13 Emyko called and said her husband was too busy to participate	**Unable to participate**
Maas, Mathias	Native Books/Na Mea Hawai'i	High	7/29/13: emailed Native Books/Na Mea Hawaii info; 8/13/13:called and spoke with Mathias, said he was interested in an interview and agreed to do questionnaire;	**Interview**
Magdalena, Fred	Department of Filipino Studies at UH Mānoa (for Florentino Das info)	Low	7/25/13 sent request email; 7/25/13 Mr. Magdalena responds and refers Dr. Colmenares; 7/29/13 send thank you email	**Refers Dr. Colmenares**
Makiki Christian Church	Location adjacent to project area	High	7/23/13: sent request letter	**None**
Miller, Keao	Boy Scouts of America Aloha Council, Marketing and Development (Re: Annual Makahiki @ Ala Moana Park)	High	8/14/13 called and left message, also emailed request; 8/30/13 Keao attempts unsuccessfully to participate in online questionnaire; check website and it is operational	**Unable to participate**
Min, Steven	Ala Moana Regional Park Events Coordinator	High	8/6/13 send Mr. Min an email request; 8/6/13 receive response from Mr. Min, agrees to participate; 8/12/13 provides a spreadsheet with permitted parks activities	**Sent info via email**
Mayor's Office of Culture & the Arts	Could provide knowledgeable individuals	Medium	7/23/13 sent request letter	**None**
Neal S. Blaisdell Complex	Arts and Entertainment venue in Kaka'ako	High	7/23/13 sent request letter	**None**
Nickell, Abigail	MADD, State Executive Director (Re: MADD memorial at Kaka'ako Waterfront Park)	High	7/23/13 sent request letter; 8/13/13 completes online questionnaire	**Online Questionnaire**
Ola Nui!	In project area	Medium	7/23/13 sent request letter	**None**
One Love Ministries Calvary	In project area	Medium	7/23/13 sent request letter	**None**
Pan Pacific Festival	In project area	Medium	7/25/13 sent email request	**None**
Prieto, Mealii "Mae"	Honolulu Powwow Committee Oahu Intertribal Council, President (Re: Honolulu Powwow @ Thomas Square Park)	High	7/25/13 sent email request; several email exchanges from 8/13/13-8/29/13; 8/30/13 Ms. Prieto sends email explaining she lost the inputted data in the process of submittal of online questionnaire	**Unable to participate**
Soares, Dexter	Interviewed, in Elison (2013)	Medium	8/7/13 sent request letter	**None**

Kaka'ako Transit Oriented Development Supplemental Cultural Impact Assessment - Cultural Informants

Name	**Affiliation/Association**	**Priority**	**Contact Log**	**Participation**
Stone, Marissa	Kewalo Marine Laboratory	Medium	7/25/13 sent email request; 7/31/13 forwards email to principal investigators at Kewalo Marine Lab; no response	**Forwards email to others**
Sutton, Robert	National Park Service, Chief Historian; Re: Falls of Clyde	Medium	7/25/13 sent email request	**None**
Tamashiro, Reed	Organizer for Discover Kaka'ako	Medium	7/23/13 sent request email; 8/12/2013 refers Katie Ka'anapu of Discover Kaka'ako	**Refers Katie Ka'anapu**
Thompson, Nicki	Interim Administrator State Historic Preservation Division	Medium	7/23/13 sent request letter	**None**
Ward Centers	In project area	Medium	7/23/13 sent request letter; Katie Ka'anapu is forwarded the request, but does not follow through with online questionnaire	**Unable to participate**
Wong, Jasper	POW!WOW!	High	7/25/13 sent request email; 7/25/13 Mr. Wong responds to email; 8/6/13 Mr. Wong submits online questionnaire; 8/29/13 request participation from Mr. Wong for FreshCafe as a cultural resource; 8/30/13 Mr. Wong submits online questionnaire for Fresh Cafe	**Online Questionnaire**
Wong, Michelle	Hawaii Dragon Boat Association (annual event at Ala Moana Park)	High	8/14/13 called &spoke with Michelle, she agreed to participate in online questionnaire; 8/14/13 emailed link to Ms. Wong; Ms. Wong filled out online questionnaire 8/26/13	**Online Questionnaire**
Woo, Debra	Diverse Earth Art, Kaka'ako	High	7/24/13 emailed Diverse ART to request participation; 7/24/13 received response from Ms. Woo asking for more info; 7/25/13 email more information to Ms. Woo; 8/6/13 receive response from Ms. Woo and Nicole Kealoha	**Refers Nicole Kealoha**
Woods, Thomas	Hawaiian Mission Houses, Executive Director	High	8/6/13 called Mission Houses Museum and left message; Mr. Woods returns call 8/7/13, explain purpose of CIA and he says he will check his schedule for interview appointment; no response	**Unable to participate**
Word of Life Christian Center	In project area	Low	7/23/13 sent request letter	**None**
Yamada, Lisa	Flux Magazine, Partner / Editorial Director	Low	7/24/13 sent online request for participation; 7/24/13 responds to request; agrees to view online questionnaire; 7/29/13 sends email to express that she does not feel like an appropriate respondent	**Unable to participate**

PHYSICAL CHARACTERISTICS OF THE CAPITAL HISTORIC DISTRICT

The Capital Historic District has three major characteristics that individuate and define it as a unique urban area. These characteristics are:

1) Open space to building mass relationship: the district encompasses a 57 acre area of which 44% is open space; a building mass to open space ratio of 1 to 6.25.

2) Visual Access: The district because of its high ratio of open space to building mass, offers a 360°, 57 acre visual plane within a dense urban setting of high and medium high rise structures.

3) Architectural Character: The Capital Historic District offers the most cohesive and concentrated historic building categories in the state of Hawaii. These categories include:

a. Classical Revival
b. Romanesque
c. Spanish Mission
d. Italian Mediterranean
e. French Romanesque
f. New England Frame (Colonial Rustic)
g. French Baroque
h. Georgian (Early Republic USA)

CAPITAL DISTRICT BOUNDARIES[1]

1) The Hawaii Capital Historic District is an area that defines the central nexus of Honolulu.

2) The Hawaii Capital Historic boundaries are defined by the outlined area on the Capital Historic District map.

[1]All street boundaries unless otherwise noted extend to the center of the named street.

STATEMENT OF SIGNIFICANCE

ARCHITECTURAL SIGNIFICANCE OF HAWAII STATE CAPITOL DISTRICT

HISTORICALLY AND TRADITIONALLY THERE has existed a centralization of all levels of government in Honolulu (refer to statement of historic significance).

This early centralization of government has resulted in an extraordinary concentration of public and private architecture reflecting the social and political evolution of the people of Hawaii. To quote Charles E. Peterson[1] "There are few cities in the world that have as many buildings dating from the first quarter of the century of their founding; and all within walking distance of one another," it is fortunate that so much is included in an area small enough to be covered by foot." The Capitol District is much more than a historic place of government and private buildings, it is also a place of trees, shade and relative quiet; a place away from the city within the city. This district is a green open island standing between the high density business district of downtown Honolulu and the hustling, bustling tourist-automobile dominated envirnment of Waikiki. The Capitol District and its present environs are an invaluable natural and cultural asset to the people of Hawaii.

[1] Charles E. Peterson is a member of the American Institute of Architects, past president of the Society of Architectural Historians, former member of the Philadelphia Historical Commission and adjutant Professor of Architecture at Columbia University.

HISTORIC SIGNIFICANCE OF HAWAII STATE CAPITOL DISTRICT

Historically, the Capitol Historic District is eligible for inclusion on the National Register of Historic Places because of its significance in association with events that have made a significant contribution to the broad patterns of our history; and because of its association

BUILDING DESCRIPTIONS

THE HAWAII STATE CAPITOL BUILDING #1

BACKGROUND:
The Hawaii Capitol building was designed for the people of the State of Hawaii by the architects Belt, Lemon, and Lo in association with John Carl Warnecke and Associates.
Initial planning began in 1959; ground was broken November 10, 1965. The building was dedicated on March 15, 1969.

OVERVIEW:
The Capitol Building is sited on a full city block that joins without interruption (on the makai side) the grounds of the Iolani Palace. On the ewa and Diamond Head sides the site is bordered by Richards St., and Punchbowl St. South Beretania St. is the mauka boundary.

ARCHITECTURAL DESCRIPTION:
Exterior:
The Capitol building is a structure of steel reinforced concrete and structural steel. The building is rectangular with dimensions of 360 ft. X 270 ft. The 360 ft. lengths are the makai and mauka sides. The building's height is 100 ft.
It was the intention of the architects that the building's various components read as sign/symbols relating to Hawaiian natural, and cultural phenomena.[1] The building is a composite of major motivated terms; terms that construct a Markoff chain[2] of linked design components.

1

2 Weaver, "Recent contributions to the Mathematical Theory of communications," P. 267 "A system which produces a sequence of symbols (which may, of course, be letters, musical notes or signs, say, rather than words) according to certain probabilities is called a stochastic process and the special case of a stochastic process in which the probabilities depend upon the previous events is called a markoff process or a markoff chain."

These components are:

SIGN	SIGNIFIER
1. Rectangular pool surrounding and enclosing the building.	Ocean, surrounding the islands, inference is to the islands of Hawaii and surrounding sea.
2. 40 reinforced concrete columns originating from the pond terminating and supporting the fourth floor (entabulature).	Coconut palms, inference is to the relationship of the coconut palm to early Hawaiian economy and culture.
3. Conical shaped ceramic tile legislative chambers.	Volcano, inference is to geological formation of Hawaiian islands.
4. Interior lobby open on the makai and mauka sides; roof opened to the sky.	Open society, inference to the acceptance of all aspects of the natural and cultural environment.
5. Reinforced concrete fourth floor overhang.	Inference is to the Greek entabulature and western architectural motivators.

Interior:

The main entry is through the mauka facade. The main lobby is an unobstructed space open to the mountains, sea, and sky. Legislative chambers are on the ewa and Diamond Head sides of the lobby. Elevators; one in each corner of the building give access to the second, third, and fourth floors.

The upper floor contains the offices of the Governor and Lt. Governor.

Architectural Significance:

The Hawaii State Capitol building is the single most dominant work of public architecture in the State of Hawaii. When the State Capitol building was conceived, it was not meant to be just another modern structure. The building was intended to reflect Hawaii and its people.

To quote from an address given by Governor John A. Burns, "The open sea, the open sky, the open doorway, open arms and open hearts - these are the symbols of our Hawaiian heritage. In this great State Capitol there are no doors at the grand entrances which open toward the mountains and toward the sea. There is no roof or dome to separate its vast inner court from the heavens and from the same eternal stars which guided the first voyagers to the Primeval beauty of these shores. It is by means of the striking architecture of this new structure that Hawaii cries out to the nations of the Pacific and of the world, this message: We are a free people.....we are an open society.....we welcome all visitors to our island home. We invite all to watch our legislative deliberations; to study our administrative affairs; to see the examples of racial brotherhood in our rich cultures; to view our schools, churches, homes, businesses, our people, our children; to share in our burdens and our self-sorrows as well as our delights and our pleasures. We welcome you! E Komo Mai! Come In! The house is yours!"

THE ARMED SERVICES YMCA #7

The Armed Services YMCA was designed by San Diego architect Lincoln Rogers in conjunction with the local Honolulu architectural firm of Emory and Webb. The building was dedicated March 16, 1928.

Overview:

The Armed Services YMCA building stands at the corner of Richards and Hotel Streets; which was the original site of a Royal Hawaiian Hotel which was used as the YMCA.

ARCHITECTURAL DESCRIPTION:

Exterior:

The building's plan is U-shaped with a central court (with an open second story lanai overlooking the makai end of the central open court) containing a swimming pool with surrounding deck lanais. The building's roof is a low ridge hip with green glazed straight mission barrel tile surfacing.

The building is constructed of steel reinforced concrete and structural steel.

CONTINUATION SHEET ITEM NUMBER 7 PAGE 6

Fenestration is symmetrical and in parallel runs of metal frame casements. The broad overhang roof eaves are painted on the undersides with abstract Mediterranean design motifs.

The entry portico is fashioned from cut and finished coral, the portico consists of three flat arched entryways, the entryway surrounds are of rusticated coral block with four engaged moresque columns supporting segmented freestanding Triglyphs; immediately above each doorway's flat arch is a large cartouche with base relief symbols representing the three branches of the armed services.

Above the main entry portico is an open groin vaulted loggia that traverses the second story frontispiece to join the projecting half-round open loggias at either end of the portico.

The YMCA is five stories in height; with a fifth floor open loggia (supported by metal Corinthian columns) surrounding the entire fifth floor.

Interior:

Entry through the main portico gives access to central lobby with hotel like check-in desk and general lounge area. The first floor contains a gymnasium, games hall, restaurant, locker rooms, barbershop, tailor shop, curio shop and billiard room. The second floor contains various game rooms and public/private meeting spaces. The third through fifth floors contain two hundred and sixty-eight sleeping rooms.

Architectural Significance:

This building is a member of a unique and declining category of buildings; it is a first generation example of major Spanish Mission architecture, and stands in direct design relationship to the Hawaiian Electric Building, the Federal Building, the YWCA, and Honolulu Hale. At this time, the YMCA and Julia Morgan's YWCA are the only buildings in the city core area offering open and unrestricted social leisure services to the core city population.

The YMCA is an important social and physical factor in the generation of the sense, both spacially and physically of the Capitol District.

Current State of Repiar: Good to excellent.

THE HAWAIIAN ELECTRIC COMPANY DOWNTOWN OFFICE #9

The Hawaiian Electric Company building is of Mediterranean derivation. The building was designed by New York architects York and Sawyer with local assistance from the Honolulu firm of Emory and Webb, and was completed in 1927 at a total cost of 750,000 dollars.

Overview:

The Hawaiian Electric Building fronts Richards Street and is bounded on the east by South King Street; to the west by Merchant Street.

ARCHITECTURAL DESCRIPTION:

Exterior:

The Hawaiian Electric Company is a four-story building of trapezoidal plan. The building is constructed of reinforced concrete and steel framing; the roof form is a composite of hip, gable, and flat with parapet, the hipped/gabled roof sections are surfaced with straight barrel mission tile.

The outstanding exterior features are the ground floor story and half stilted arched windows with Churriguera[1] decorated column supports, and the makai, Diamond Head corner cupola with its low rise polygonal tiled roof and lantern.

The second and third story windows are rectangular metal framed casements with stone sills. The third floor windows are arched and set in groups of two with a full major arch surround: there are three such groupings on the Richards Street facade, and eight grouping on the King Street facade. There is a three bay groin vaulted entry portico on the ground floor of the Richards Street facade with a hand painted ceiling by Julian Jarnsey.

[1]Characteristic of the forms introduced into Spanish architecture by Churriguera, Ribera, and other designers early in the 18th century. A good illustration of the form can be seen in Trent Elwood Sanfords, The Architecture of the Southwest, Greenwood Press, plate 27.

NATIONAL REGISTER OF HISTORIC PLACES
INVENTORY -- NOMINATION FORM

FOR NPS USE ONLY
RECEIVED JUN 13 1978
DATE ENTERED DEC 1 1978

CONTINUATION SHEET ITEM NUMBER 7 PAGE 8

Interior:

There are three entries and exits, the main entry is to the rear (ewa end of the building). There is an arched entry on either side of the building giving access to a vaulted hallway/mall, this hallway bisects the ewa end of the building and acts as a central foyer coordinating (spacially) the first floor spacing. The stairwell leading to the second and third floors originates from the ewa Hallway. The third entry is through the Richards Street portico, and gives access to the general service offices of the main ground floor space. This space has a richly decorated (Plaster mouldings/hand painting) coffered ceiling done by J. Rosenstein. The upper floors contain general administration offices as well as the Hawaiian Electric Company library.

STATEMENT OF SIGNIFICANCE:

The Hawaiian Electric Building has some of the architecturally most elegant interior spaces of any buildings or building in the State of Hawaii. The richness of the decorated plaster, sculptured and hand painted ceilings, the fine detail of the Churriguera stonework, and the combination of wrought iron and brass fitting, grill work and gates used throughout the building lend a character of refinement to the structure of the building that will never again be seen in commercial architecture. This is a rare and intelligently articulated example of Spanish Colonial Architecture.

CURRENT STATE OF REPAIR: Excellent

STATE TERRITORIAL OFFICE BUILDING #11

Background:

The Territorial State Office Building was designed for the United States Federal Government by architect Arthur Reynolds in 1926 to house the Hawaii Territorial Administrative offices.

Overview:

The Territorial State Office Building is sited at the corner of King and Punchbowl Streets directly across from the Hawaii State Library and adjacent to the Judiciary Building, Aliiolani Hale.

Form No. 10-300a
(Rev. 10-74)

DATE ENTERED DEC 1 1978

CONTINUATION SHEET ITEM NUMBER 7 PAGE 9

ARCHITECTURAL DESCRIPTION:

Exterior:

The structure is six stories in height, rectangular in plan and has a flat asphalt roof with penthouse structures.

Construction materials are: reinforced concrete, and structural steel. The building is constructed of two major architectural elements: at grade there is a two story (with basement) horizontal architectural element which acts as base for a vertical element rising a full six stories. The vertical element is centered from ewa to Diamond Head on the horizontal element. The two story horizontal element extends 67 feet on either side of the vertical element. Exterior windows are double-hung and run in symmetrical parallel rows.

Exterior wall surface treatment consists of pilasters marking windows divisions and terminating in classical cornices. The buildings frontispiece is marked by a massive straight stair with double landings leading to the segmental archway-entry with heavy protruding imposts. Above the archway there is a five foot beaked architrave with terminal taenia[1] supporting two massive full round corinthian columns extending three stories in height terminating in the sixth story entablature.

Interior:

Entry is gained through either the mauka or makai facades. The main entry being the mauka entry.

The dominant interior space is the central lobby with second story mezzanine and leaded glass decorative dome; the dome design is a graphic depiction of the coat of arms of the Hawaii Territory. The interior spaces, other than the main lobby, are simple unadorned offices and administrative spaces of no architectural consequence.

STATE OF SIGNIFICANCE:

The major environmental asset of this structure is its location within the Capitol District area; the building and its grounds blend, and add to the total texture, scale, and historic character of the Capitol Distric

[1] Taenia (tee'nea) the fillet separating the Doric frieze from the architrave.

CONTINUATION SHEET ITEM NUMBER 7 PAGE 10

HAWAII STATE LIBRARY #12

Background:

The Hawaii State Library was designed for the Territory of Hawaii by New York architect Henry D. Witfield in association with Honolulu architect H. L. Kerr. The design was commissioned in 1909, the building was completed in February 11, 1913.

Overview:

The Hawaii State Library is sited on Punchbowl Street directly across from Honolulu Hale.

ARCHITECTURAL DESCRIPTION

Exterior:

In plan the Hawaii State Library is quadrangular with an open central court.

The roof structure is a hip design, with green glazed Tuscan clay tiles. The library's main entry faces King Street and is approached via a fifteen foot wide brick edged asphalt walkway crossing a green grassy open lawn. The walkway terminated at a broad stairway of six rises leading to a main portico landing. The portico is supported by eight reinforced concrete Tuscan columns (20 feet in height). The columns support a single unadorned architrave running the full length of the three stilted arches, the center arch acting as the main entryway. These arches are eighteen feet high and have bronze inset grille work. The grille work surrounds the entry doors. On either side of the doors are side lights, above the doors are projected pulvinated friezes supporting bronze relief pediments. The ewa and Diamond Head facades of the Library are simple white plastered walls with pilasters marking wall divisions containing four rectangular double-hung windows. The mauka dacade has an entry drive-up (loading and unloading) approach to the interior courtyard.

Interior:

The main lobby is covered by a 16 X 30 foot coffered ceiling with

CONTINUATION SHEET ITEM NUMBER 7 PAGE 11

skylight. A second story mezzanine overlooks the lobby. The lobby contains the book checkout desk, various tables, chairs, and bookracks. Directly through the lobby one enters the central court, an ivory covered open space with bisecting walkways, and a surrounding first and second story loggia. In all of this is an extremely pleasant space, a place of cool and relaxing spaces shaded by flowering trees, and the overhangs of the loggia ceilings. Both the Diamond Head and ewa wings contain the Hawaii Library books collection, as does the mezzanine King Street floor.

ARCHITECTURAL SIGNIFICANCE:

There are two points of major significances:

1. The location and scale of the structure is a supplemental element to the total sense/character of the Capitol District. The Hawaii State Library occupies a pivotal position within the architectural landscape of the Capitol District; in conjunction with the Iolani Palace, this building stands at the center of the Capitol District and creates an architectural scale counterpoint to the buildings surrounding the Iolani Palace grounds.

2. Of particular architectural note is the use of bronze grille work insets in the arches of the main entry, this is the only example of this particular architectural treatment in the State of Hawaii. Also of note is the architect's strict adherance to classical design principles (except for the inclusion of the Roman derivative arched portico element with bronze grille work).

Site:

The Hawaii State Library site is level and runs from South King Street to the State Capitol Building grounds mauka/makai. The Library is set back some 123 feet from South King Street and 35 feet from Punchbowl Street. The grounds run uninterrupted to the grounds of Iolani Palace forming a continuous and expansive landscape.

The site is well tended and planted with various indigenous shrubs, flowering plants and trees.

PRESENT CONDITION: Good to excellent.

CONTINUATION SHEET ITEM NUMBER 7 PAGE 12

HONOLULU HALE AND GROUNDS #13

Background:

Honolulu Hale was designed by architects C. W. Dickey, Hart Wood, Robert G. Miller, Guy Rothwell and Marcus C. Lester. The building was opened for city use November 26, 1929. It was built for and has continued to serve as the City Hall of Honolulu. The city government long ago outgrew Honolulu Hale; but it continues to house the Mayor's office, City Council and principle staff agencies.

Overview:

Honolulu Hale is sited on the corner of King and Punchbowl Streets, directly across Punchbowl Street from the Hawaii State Library.

ARCHITECTURAL DESCRIPTION:

Honolulu Hale is four stories in height with a single six story tower fronting Punchbowl Street. The building's plan is rectangular. Construction materials are reinforced concrete and structural steel. The roof design is complex, a combination of sheds and hips intersect forming a variety of roof shapes. Roof surfacing material is terra cotta clay tile.

Honolulu Hale's main entry is through the King Street facade. There are three basket arched entryways with compound rectangular portal insets. On the exterior and above the arched entryway is an open balcony running the length of the building. The Punchbowl Street facade is marked by the six story tower with its tile polygonal low rise roof. This tower is medieval in design character, small window penetrations supporting hood moulds, and carved stone balconies. This facade is complex in design and has an assortment of open and closed balconies, loggias, asymmetrical fenestration, deep recessed casement windows, flush metal double-hung windows, windows with cast concrete grille work, open and closed arched windows; similar fenestration is employed on the King Street facade.

Interior:

Entering the building through the King Street facade, there is an open central court with grand stairway leading to the fourth floor mezzanine

CONTINUATION SHEET ITEM NUMBER 7 PAGE 13

at the mauka end of the cental court. The central court has a painted and highly ornate coffered ceiling with the central ceiling section open to the sky. The interior treatment of the central court is reminiscent of an Italian Bargello[1] of the Middle Ages. The carved stone work on the columns, interior and exterior balconies and general decorative trim is the work of the Italian sculptor, Mario Valdastre[2]. The nonpublic interior spaces are used by the various branches of government.

STATEMENT OF ARCHITECTURAL SIGNIFICANCE:

Honolulu Hale is a prime example of first generation Hawaii adapted Spanish Colonial/Italian Architecture; it is a massive structure, yet projects a sense of human scale that is a hallmark of the Hawaii adapted Spanish Colonial Architecture.[3]

Honolulu Hale along with the YMCA, YWCA, the Federal Building, the Tax Office Building, and the Hawaiian Electric Building set the precedent of architectural scale for the Hawaii Capitol District.

Throughout the nineteen twenties local architects (after being influenced by mainland architects York and Sawyer, and Bertrum Grovsner Goodhue) for the first time self-consciously approached the question of an indigenous architectural design characteristic for Hawaii. From 1921 until the middle 20's there was a drive toward Italian, Spanish Colonial, Spanish Mission architectural forms. During the 30's and in the hands of Hart Wood (and influenced by B. G. Goodhue's Honolulu Academy of Arts building) the Spanish Colonial and Mission style became the Hawaiian style with the adaptation of the high ridge hip roof. Honolulu Hale represents an extremely unique aspect of this architecturally historic building phase in Hawaii.

[1] Headquarters of an army watch or civil police.

[2] Mario Valdastre was brought to Hawaii by San Francisco architect Julia Morgan to work on her YWCA project. Vladastre stayed on in Hawaii for forty years, and then retired, with his wife in Northern Italy. He has recently come out of retirement, and returned to Hawaii to work on the Iolani Palace.

HONOLULU HALE ANNEX/THE MISSION MEMORIAL BUILDING AND ANNEX #14

The Mission Memorial Building and Annex were commissioned and built for the Hawaii Evangelical Association. The Mission Memorial Building and attached auditorium were constructed during the period 1915-1916 in commemoration of the approaching centennial anniversary of the arriving first missionaries. This structure was designed by architect H. L. Kerr. The mission annex was completed January 12, 1930 and dedicated April 11, 1930. The structure was designed by architect Mark Potter.

Overview:

These buildings are sited on King Street between Honolulu Hale and the City and County Building.

ARCHITECTURAL DESCRIPTION:

The Mission Memorial Building is two stories in height and rectangular in plan. The roof is a low pitched mansard with newel post balustrade parapet.

Structure:

The building's foundation is reinforced concrete from the water table to six inches above grade. Walls from the foundation upward are of mortar bound English Bond red brick and reinforced concrete. Windows are metal frame double-hung rectangles with white painted concrete sills and lintels. The King Street and ewa facades have roof joining over-hung pediments that are the porticos for the King Street main entry and the ewa side entry. These porticos are supported by five free-standing tuscan columns with Ionic capitals. The Diamond Head facade has a two story half round portico enclosed on its second level. This portico is supported by six concrete saddle backed dormers with arched single hung windows. The porticos enclosed second level has full glass walls and a wrought iron balustrade. The ground floor level has a simple rectangular entry door with concrete lintels. The rear of the building has an open colonnade connecting the Mission Memorial Building with its auditorium.

Interior:

Entry to the building is gained through either the ewa or Diamond Head

porticos. The original King Street entry has been closed off and its interior spaces have been converted to offices. The interior of the building has been extensively altered to accomodate various administrative facilities; further alterations to the interior spaces are forthcoming. Access to the second story is gained via a stairway which has an interesting decorative wrought iron handrail. The second story has been extensively altered, but of interest is the overhead skylight with intricate tracery. Unfortunately this skylight has been roofed over.

STATEMENT OF SIGNIFICANCE

This building is styled in the manner of Georgian REVIVAL Architecture. The Georgian style denotes a British architectural period during the reign of Ann and the Four George 1702-1803. This style was to be the prominent architectural style (for major buildings) during the early republic period in the United States 1702-1830. The style was also known as Neo-Classical, and Jeffersonian Classicism, (also to be called Roman Revival). The Mission Building and its side buildings are the only examples of Jeffersonian Classicism in the State of Hawaii. These buildings encompass a unique architectural category and should be considered valuable.

MISSION MEMORIAL AUDITORIUM

Background:

The Mission Memorial Auditorium was designed by H. L. Kerr as a support facility (auditorium) for the Mission Memorial Building. It was dedicated with the Mission Memorial Building in April 1916.

Overview:

This building is a single-story structure sited on the mauka side of the Mission Memorial Building. It is attached to the Mission Memorial Building by a colonnade supported by concrete Corinthian columns.

ARCHITECTURAL DESCRIPTION:

Exterior:

The Auditorium building has an asphalt shingled hipped roof. The

building's structure is reinforced concrete with red brick English bond surfacing, windows are metal double-hung, with sill set on grade and terminated at the roof eaves.

Interior:

Entry is gained via the colonnade portico. The interior space has been extensively altered. The once high auditorium ceiling has been lowered to accomodate a more comfortable office atmosphere. The building at one time had a stage traversing the mauka end of the auditorium, this stage has been paneled and converted into office space.

STATEMENT OF SIGNIFICANCE:

This building's significance is the same as that expressed for the Mission Memorial building.

MISSION MEMORIAL ANNEX

Background:

This structure was designed by architect Mark Potter. The cornerstone was laid January 12, 1930. The building was dedicated April 11, 1930. The Annex's original use was as the Christian Education Building.

Overview:

The Mission Memorial Annex is on the Diamond Head side of the Mission Memorial building and auditorium.

ARCHITECTURAL DESCRIPTION:

Exterior:

The Annex building has an asphalt shingled hipped roof. The building's frontispiece is two stories in height and extends a bays width on either side of the two story frontispiece. The annex is constructed of reincorced concrete with red brick English Bond surfacing, its metal windows are double-hung and have white concrete sills and lintels. There are two entries: one in the frontispiece, and one to the rear of the building. The main entryway has a classical surround composed of two Ionic columns with a simple unadorned entabulature.

Interior:

At this time (August 27, 1975) the interior is being extensively remodelled, there is little left of the original interior spaces except the stairway leading to the second story. This stairway has a well formed wrought iron handrail.

ARCHITECTURAL SIGNIFICANCE:

Same as the Mission Memorial and auditorium buildings.

TAX OFFICE BUILDING (HALE AUHAU) SHPO # 21

Background:

Hale Auhau is a State Office building designed by Public Works architect, Harry K. Stewart. The building was completed in 1939.

Overview:

The structure is sited on Queen Street between Mililani and Punchbowl Streets directly across Queen Street from the Kapuiwa Building.

ARCHITECTURAL DESCRIPTION:

Exterior:

The building is a three-story reinforced concrete structure. The roof is hipped and surfaced with terracotta tile, the roof hip rafters are 'broken' to generate a Japanese roof design effect. The structure's plan is a closed 'I' with the length facing Queen Street.

Hale Auhau has two dominant architectural features:

1. The entry portico which spans the length of the Queen Street facade tying the two parallel end wings of the 'I' plan together. The portico is 17 x 40' and has square cut and finished coral columns supporting a simple stylized architrave.

2. Concrete grille work: Various windows have inset cast concrete grilles of a Hawaiian design derivation. Exterior window fenestration has two forms: from grade and extending to the third floor are two story arched windows, third story windows are simple

CONTINUATION SHEET ITEM NUMBER 7 PAGE 18

rectangular casements. The use of two story windows extending through the first and second floors gives the impression of a two story building rather than a three.

Interior:

The building is entered through the main portico. Entry doors are metal and glass of 'modern industrial design.' The main interior space is a two story rotunda. The rotunda is bordered by service counters that give access to the various office personnel on the first floor. The first floor is an open unpartitioned space penetrated by concrete structural columns.

The second story is gained by a stairway to the rear of the rotunda. The second floor is identical in construction to the first. Unobstructed, unpartitioned space with penetrating columns (but with no central rotunda access).

The third floor contains a courtroom, and various office and supply rooms.

Site:

Hale Auhau is sited on a level well-tended grassy lot. Plants consist of palms, and one large monkey pod tree.

STATEMENT OF SIGNIFICANCE:

The significance of Hale Auhau rises from its close design relationship to the other Spanish Mission and Colonial buildings within the Capitol District. In and of itself, the Tax Office Building is of no great architectural merit. It is a second generation derivation of the original 1920's Capitol District Spanish Mediterranean architecture, but it does maintain and support the overall texture and design sense of the Capitol District and this is an important feature (within a district) as individual architectural merit.

CURRENT STATE OF REPAIR: Good to excellent

with the lives of persons significant in our past. After 1845, as Gavan Daws has written, "It was true enough throughout that period (1845 - present) to say that what happened in rural Oahu and on the outer islands might have nothing but local significance; what happened in Honolulu might very well affect all Hawaii."[1]

1
R. Warwick Armstrong (ed), Atlas of Hawaii (Honolulu: University Press of Hawaii, 1973), P. 90

In pre-contact Hawaii, the area of Oahu now encompassed by the city of Honolulu had some importance as a place of sacrifice (Punchbowl), as a food gathering center (the fishponds of Moanalua and Halawa), and as a place of residence for Oahu alii (Waikiki). However, it was not until after 1794, when Western mariners recognized the potential value of Honolulu's deep and protected harbor that it began to achieve primary importance as a commercial, urban, and government center.

In the period of time after unification of the Hawaiian archipelago by Kamehameha I, it can be said that capitol existed wherever the king happened to be. Kamehameha I, II, and III enjoyed travelling around the islands on progressions similar to those of the English Plantangent kings, sampling the hospitality and loyalty of their subjects, and accompanied by a large retinue that tended to deplete the resources of the areas they visited.

The Hawaiian monarchs did not fail to recognize the importance of Honolulu, however. Kamehameha I established harbor fees and controlled the growing commerce centered there. During his residence in Honolulu from 1804 to 1811, the town became firmly established as an economic center.

The advent of the sandalwood trade, whaling, and the establishment of Christian missions after 1820, led to a greater influx of Europeans. Most settled in Honolulu for economic reasons. From the time of the death of King Kamehameha I in 1819 through the short reign of Kamehameha II and into Kamehameha III's rule, problems caused by the clash of Western business and religious interests and Hawaiian

CONTINUATION SHEET ITEM NUMBER 8 PAGE 2

customs grew. The old style of Hawaiian government which had worked fairly well under Kamehameha I, proved unable to cope with these new problems by the time of Kamehameha III. One problem in particular was that of the lack of a permanent place of government, where representatives of the Western nations and the Hawaiian government could meet.

In 1838, the ruling chiefs appointed William Richards, an American missionary to serve the Hawaiian government as an advisor. Afterwards, other Western advisors were appointed to government posts such as Dr. Gerrit Judd, John Ricord, and Robert C. Wyllie. They saw the necessity of reinforcing the position of the king in every way possible while also establishing the rudimentary forms of parliamentary democrary.

They established formal systems of court etiquette, and more importantly, convinced the king and the chiefs of the need for a permanent capitol. Kamehameha III preferred Lahaina, Maui, which since the arrival of foreign whaling shops in 1820, had become a boom town. In the long run, however, Lahaina with its open roadstead, subject to the vagaries of wind and current, could never compete with Honolulu. Finally, in February, 1845, Kamehameha III moved permanently to Honolulu and established his residence on the approximate site of the present Iolani Palace. In May 1845, he formally opened the legislative session in Honolulu with a speech from the throne. Five years later, Honolulu was officially proclaimed the capitol of Hawaii.

The first Iolani Palace was constructed by Charles Kanaina in 1845, and was located on the grounds of the present Iolani Palace. It was of coral blocks, one story in height, and was used by Kamehamehas III, XV, IV, and V, as well as Lunalilo and Kalakaua before being torn down by the latter monarch to make room for the present Iolani Palace.

In 1850, funds were appropriated by the legislature for the construction of a Court House. Work began on it in 1851, and it was completed in 1852, with most of the work being done by convict-labor. It served as the actual place of business. Located on Queen Street, between Fort and Bishop Streets, it served as the actual place of business for the Hawaiian government until the

construction of Aliiolani Hale on King Street, between Richards and Punchbowl, in 1874.

Prior to the construction of the Court House, and the movement of the capitol to Honolulu, other structures were built in the Capitol Historic District that tended to establish it as a center of importance. In 1820, the first Christian missionaries constructed their mission on land deeded to them by Governor Boki of Oahu. This land was at the present site of Kawaiahao Church, at the corner of Punchbowl and King Streets Makai-Diamond Head. In 1821, the first wood frame mission house was completed, adjacent (Diamond Head) of the mission. In 1823, a coral-block structure was built to contain the mission's printing press. The third missionary building is the Chamberlain House, completed in 1831, also of coral block construction. The missionary enclave at this location became headquarters for the missionaries throughout Hawaii. This tended to centralize the Protestant religious structure government at the Capitol district, and thus give the area additional importance.

In 1825, the bodies of King Kamehameha and his wife Kamamalu were interred in a coral house built on what is now the Iolani Palace grounds. The bodies remained there until 1865, at which time they were transferred to the Royal Mausoleum in Nuuanu Valley.

Im 1835, an adobe schoolhouse was constructed by the missionaries behind the mission church. In 1842, the present Kawaiahao Church was completed at the site of the original mission. Only a year later, the Roman Catholic Our Lady of Peace Cathedral, was completed on the Mauka-Ewa corner of the capitol district. This church was the headquarters for the Roman Catholic Dioscese of Honolulu.

In 1846, Captain John Dominis, an American, completed his home, located on the Mauka side of Beretania Street, across from the present State Capitol building. After his death, it passed on to his heirs, including his son's wife, Princess Liliuokalani. She lived in it until her death, after which it was purchased by the Territory of Hawaii for use as the Governor's mansion, which is its present use. It is the oldest continually-occupied structure in the State. All of this construction tended to establish an aura of importance to the area of the proposed Capitol Historic District.

CONTINUATION SHEET ITEM NUMBER 8 PAGE 4

The Iolani Barracks were built in 1871 to house the Royal Household Guard. The architect was Theodore Heuck, a German. The barracks were originally located on what is now Hotel Street, but were moved in 1965 to make way for the new State Capitol building.

In 1874, Aliiolani Hale, constructed to house the expanding Hawaiian government was opened despite complaints that it was located so far out of town, and was much too large. This structure, originally designed as a palace by Thomas Rowe, an Australian architect, was altered in the planning stage by Robert Sterling, the Superintendent of Public Works, to become a parliament-government office building. In 1893, Iolani Palace became the "Executive Building," and Aliiolani Hale became the "Judiciary Building."

St. Andrews Cathedral, designed in Britain by B.F. Ingelow, was begun in 1867 as a memorial to King Kamehameha IV. Funds for the cathedral were raised the King's widow, Queen Emma. Completion of the construction called for in the original plan was in 1902.

In 1882, construction of the new Iolani Palace, the centerpiece of the Historic Capitol District, was completed. It was the only royal palace in the United States. It served as a place of residence for its builder, King David Kalakaua and later, Queen Liliuokalani, until the overthrow of the monarchy in 1893.

A bandstand was constructed on the grounds in 1883. The Provisional government occupied the palace with its offices after the revolution, and named it the "Executive Building." Legislative sessions were held in the structure form 1895 until 1968, when the new state capitol building was opened. At present, Iolani Palace is undergoing a total restoration and will open in 1978 as a museum.

In 1884, the Kapuaiwa Building was constructed to house government records. It was named after Kamehameha V (Lot Kamehameha Kapuaiwa). It never served as a record center, however, and was instead used to house government offices which could not be fitted into Aliiolani Hale.

The next public construction occuring in the Capitol Historic District was the Attorney General's Buildigg (Old Archives Building),

completed in 1906. This building was constructed to house public records, and was designed by the noted architect O. G. Traphagen. It was the first building in the United States built for the express purpose to serve as an archives structure.

The Hawaii State Library building on the Mauka-Ewa corner of Punchbowl and King Streets was completed in 1913 from a design by Honolulu architect H. L. Kerr and New York architect Henry Witfield.

The Mission Memorial Building was dedicated in 1916 as a memorial to Protestant missionaries who first arrived in Hawaii in 1820. It was used by the Hawaiian Board of Missions as a headquarters. In 1945, the City and County of Honolulu purchased it, but leased it to the mission board until 1947, when City and County offices were moved into it.

In 1922, the first Federal construction in the Historic Capitol District was completed--the U.S. Post Office, on Richards Street, and nect to Aliiolani Hale.

In 1926, the Territorial Office Building was completed. It was designed by Arthur Reynolds to house the offices of the expanding territorial government, but was generally not well received by architectural critics.

The Hawaiian Electric Company building, on the corner of Richards and Merchant Streets, was completed in 1927. This attractive structure, designed by York and Sawyer, the same New York architects who designed the U.S. Post Office building across Richards Street from it. The building was obviously influenced by the public architecture predominant in the Historic Capitol District in terms of size, scale, and texture.

In 1927, the Young Women's Christian Association building on Richards Street, across from Iolani Palce, was completed. This graceful, Mediterranean-style building was designed by the noted architect, Julia Morgan. The structure is compatible with the Historic Capitol District in terms of size, scale, and texture.

CONTINUATION SHEET ITEM NUMBER 8 PAGE 6

The Army and Navy Young Mens Christian Association building on the corner of Richards and Alakea was completed in 1928. It was built on the site by local architects Emory and Webb, and San Diego architect Lincoln Rogers. The Mediterranean-style structure is also compatible with public architecture in the Historic Capitol District in terms of size, scale, and texture.

The City and County of Honolulu's city hall building, "Honolulu Hale", was completed in 1929. Designed by local architects C. W. Dickey, Hart Wood, and Robert Miller, Guy Rothwell, and Marcus Lester, it reflected the current vogue in Mediterranean-style architecture.

Public and private construction has continued in the Historic Capitol District down to the present time. For the most part, the design of this construction has been such that the scale and texture of the district has maintained its historic character. Other buildings erected in the Capitol Historic District are: the State Tax Office, on Queen Street, across from the Kapuaiwa Building (1939), the Tax Office Annex (I'i Building), adjacent to the Tax Office (1950), the Mission-Historical Library building, makai of the Mission Houses Museum (1950), and of course, the State Capitol Building (1969).

DESCRIBE THE PRESENT AND ORIGINAL (IF KNOWN) PHYSICAL APPEARANCE

Kawaiahao Church: Revered as the Protestant"mother church" of Hawaii, the building is of basilican plan with tetrastyle portico surmounted by a clock and belfry tower with castellated parapet erected over the narthex. It is constructed of indigeneous coral blocks in undulating range courses of approximately equal height.

Overall dimension: 143'-6" long by 78'-10" wide with eaves line approximately 35' above grade.

Foundations: Coral block with basement walls 44" thick to water table at first floor level. Exterior plastered with rough texture to water table.

Wall constructions: Walls to balcony levels are coral block 33" thick centered on basement wall, and above, they are 27" thick with 6" ledger on inside. Coral block routh cut to approximate equal height and variable length are laid with undulating range courses with applied mortar joints. Wall terminates with simple cornice of classic design at eaves line.

Portico and Tower: The main church entrance which is a tetrastyle portico of engaged austere stone doric columns and entablature, with center bay wider than side bays, projects slightly from the facade. This is surmounted by a belfry and clock tower with a castellated parapet erected over the narthex. A clock with a face approximately 12 feet in diameter on three sides of the tower below the belfry dwarfs the scale of the building. Clock face on fourth side over roof ridge is smaller in diameter. The belfry has one arched opening in each of four sides protected from weather by wood louvers. The portico is approached by a pyramidal range of concrete-faced coral steps terminating at a platform approximately 33 feet wide by 11 feet deep.

Doorways and doors: The main entrance doorway is a semicircular arched opening with cement plaster reveals set in the center bay of the portico and is approximately 7'-6" wide by 13' high. Double wood doors with raised panels and mouldings and a lunette fill the opening. This opening is flanked by similar but smaller semicircular arches and single doors in side bays of the tetrastyle portico.

Windows: All windows are modern replacements of anodized aluminum. Basement window openings are rectangular with variable head heights, windows at main floor are rectangular with dressed stone lintels and sash are awning type. Windows at balcony level are semicircular arched openings and awning type sash with muntins terminating in gothic forms in the lunettes. All windows have plaster reveals.

Roof Shape: Gable roof covered with slate shingles and supported by reinforced trusses and purlins exposed to the nave.

SPECIFIC DATES: 1838-42 (Church) — BUILDER/ARCHITECT: Hiram Bingham

STATEMENT OF SIGNIFICANCE[1]

Kawaiahao Church: The historical significance of Kawaiahao Church is indicated by the fact that it is often called "the Westminister Abbey of Hawaii." Outgrowth of the original Mission Church founded in Boston in 1819 and of the first foreign church on Oahu, it symbolizes the work of the Protestant missionaries, "one of the motivating forces in the life of Honolulu and the Islands." As the state church, it was the scene of many celebrated events--inaugurations, funerals, weddings, thanksgiving ceremonies--associated with the Hawaiian kingdom. Although not the oldest surviving religious structure in the islands, it, as the church founded and designed by the Rev. Hiram Bingham, seems to be the most important and representative church of the Protestant missionary period. The Kawaiahao Church, the old adobe schoolhouse on its grounds, and the three nearby "Mission Houses," form a group of structures which seems best to illustrate the influence of the American Board missionaries upon Hawaii.

Its interest in Hawaii aroused by accounts of New England mariners and by Hawaiian youths who had reached the United States and been converted to Christianity, the American Board of Commissioners for Foreign Missions decided in 1819 to expand their work to the islands. A Hawaiian Mission Church was organized in Boston during October, 1819, and almost immediately thereafter a missionary party of 17 members under the direction of the Rev. Hiram Bingham and the Rev. Asa Thurston, set sail in the brig Thaddeus. The group, less a contingent dropped off at Kailua, landed at Honolulu on April 19, 1820. Four days later Mr. Bingham preached the first formal Protestant sermon in the islands. The missionaries on Oahu were first assigned land near the Nuuanu Valley, but the king suddenly allotted them instead a tract on the duty plain near Honolulu near a spring known as Kawaiahao. The "Hawaiian Pilgrims" took up residence there in thatched houses, a part of one dwelling serving as "the first foreign church on Oahu." This meeting room also served as a school on week days, and here was begun the educational work which was to make 80 per cent of the Hawaiian population literate within four decades--a remarkable achievement with far-reaching effects upon the development of the islands.

The congregation soon outgrew the first room, and in 1821 a thatch-roofed, wooden church, 54 by 22 feet in size, was built a short distance toward the sea from the

[1]The statement of significance is taken from John A. Hussey, National Survey of Historic ites and Buildings (NSHSB) form, "Kawaiahao Church," July 19, 1962, Records of the Historic Sites Survey, Heritage Conservation and Recreation Service (HCRS).

Kawaiahao Church and Mission Houses
CONTINUATION SHEET ITEM NUMBER 7 PAGE 2

Technical Description of Interior:

Floor Plan: Basilican church plan with one aisle on each side and a balcony in the manner of contemporary New England churches, whence the missionaries came. Five square plaster finish columns range down each side of the nave at the face of the balconies surmounted by a run-plaster entablature. The balconies step down between columns toward the sanctuary.

Sanctuary: The alter reposes on a dais five steps up from the main floor, protected by a railing, approximately 16 feet ewa of the rear wall. The reredos of panelled wood erected between large arched windows in the Waikiki wall of the church sheaths the sacristy.

Pews: Pews of redwood are arranged for center aisle and side aisles which are along outside of the nave columns. The upholstred Royal Pews located at either side of main entrance against the ewa wall are handsomely guarded by panelled Koa wood railings and back boards.

Stairways: Stairways of reinforced concrete occupy the mauka and makai corners at either side of the narthex and lead to the balcony. That on the mauka side, also, leads to the basement.

Choir Loft: The choir and organ loft occupy the balcony across the ewa end of the nave and the tower room.

Site:

General setting and orientation: Church is set in a walled enclosure at the Waikiki-makai corner of Punchbowl and South King Street with church entrance to ewa. Surrounding area is landscaped with native plantings. At the rear of the church is the original Mission Cemetery and makai of the Punchbowl Street entrance is the Gothic tomb of Lunalilo.

Enclosure: The 6 foot high coral block wall erected around the church site ca. 1875 was reduced to 2 feet in 1899 to avoid repetition of the Wilcox revolution of 1889 when Honolulu Rifles fortified themselves on the church grounds and commanded the makai portion of the Palace grounds.

Lighting: Electric illumination was installed in 1893 replacing lamps, two of which fell in 1894 and started fires.

Heating: In the balmy climate of Hawaii no heating is required.

Kawaiahao Church and Mission Houses
CONTINUATION SHEET ITEM NUMBER 7 PAGE 3

Condition of Fabric: In excellent condition as, due to termite destruction, building has been resotred and altered several times since first erected 1838-42. It was completely reconstructed 1925-27, when all structural wood was replaced with reinforced concrete and steel and interior redesigned. The latest restoration was in 1965 when the exterior cement plaster applied in 1927 was removed, metal windows installed, and termite damaged wood work repaired.

Alterations: In 1867 to prepare for the installation of an organ to replace the melodion, the pulpit was moved forward some twenty or thirty feet nearly to the center of the auditorium, and a new choir loft built behind the pulpit. The new area was partitioned into Sunday school rooms. In 1873, just prior to King Lunalilo's unauguration, the church was renovated including installation of new coconut mats and securing the galleries with iron bolts to improve their safety. About 1885 a legacy from Mrs. Bernice Pauahi Bishop was used to remove the small steeple, "an absurd wooden spire," blunt and without much visual attraction. In addition, the Bishop funds were used to build up the tower with coral stone to give it the square tower its present height.[1] In 1895 electric lighting was installed. At the same time a renovation was carried out involving the replacement of the wooden tie beams which were badly termite eaten. The interior was refitted and repaired.

In 1925 the building was almost entirely reconstructed. All interior wood was termite infested. All wood was removed leaving only the coral walls standing and the building was rebuilt from the basement up. The auditorium was restored to its full length, the galleries were widened and extended. Concrete pillars provided an aisle effect within. The reconstruction attempted to return the building to its original New England simplicity. The pulpit, with furniture made from salvaged ohia slabs and kaulia logs, was designed with wide steps leading up to it and a simple cross on the wall behind. The original arched windows on either side of the pulpit and the crescent opening above the cross were retained. New, insect-proof redwood seats were installed, and the old royal pews were closed to visitors. The roof was covered with imported slates, put on with copper nails. The outer walls were spray-coated with a cement plaster to preserve the coral blocks from damage by birds pecking at them. Inside, a new organ, funded in part by C. Brewer and Co. to commemorate their 100th aniversary, replaced the 1901 instrument. For the new, longer hall, an

CONTINUATION SHEET ITEM NUMBER 7 PAGE 4

echo section was donated by the organ manufacturer. The organ was placed in the ewa (tower) end of the building. The display pipes are visible, but the music mechanism was enclosed in four concrete rooms.

To complete the new setting, the grounds were replated - little had been done since Lunalilo's time, except in 1899 when A. S. Cleghorn pulled down the high wall, dug an artesian well, planted a lawn, and set out the line of royal palms mauka of the building as memorial to his daughter, Princess Kaiulani. A fountain pool was built with some coral block to commemorate the old spring at King and South Streets which had given the land, and the church, its name: Ka wai a Hao - the water of Hao.

In 1965, Kawaiahao underwent additional refurbishing by way of repainting and repairing the interior, repairing the slate roof, replacing the windows, and removing the 1927 cement finish from the exterior coral blocks but only to the base. Outside, the grounds were replated and the fountain rebuilt. Other improvements were planned for the future.[2]

In 1976-77 the drainage was improved by connecting the leaders to a dry well. Wainscoting and roof were repaired, the copper ridge flashing replaced and the tower reroofed. In addition, the pews and altar were refurbished, the interior painted, and continuing maintenance performed.

Frame House:[3] The mission frame house stands on the mission grounds near Kawaiahao Church on King Street. It was one of the first frame buildings to be constructed in the Hawaiian Islands. The timbers of Maine white pine were cut and fitted in Boston in 1819 and came around the Horn on the brig Thaddeus with the pioneer mission company in April 1820. The frame of the house arrived on Christmas morning of that year on board the ship Tartar.

GENERAL STATEMENT

Architectural interest and merit: One of the most interesting architectural facts about this particular structure is its literal New England origin.

[2]Description of the building and the alterations is taken primarily from "Photographic-Data Book Report," Historic American Buildings Survey record file HA-14, "Kawaiahao Church" prepared by A. Lewis Koue, FAIA, February 1967.

[3]The description of the frame house is taken from the Data Sheets filed with the HABS, file HA-21, "Mission Frame House," prepared by Woodrow W. Wilkins, August, 1967. The file contains copies of the HABS field notebooks which have detailed measurements and floors. These are included here by reference as are the series of photos including copies of historic photos and sketches.

CONTINUATION SHEET ITEM NUMBER 7 PAGE 5

Lumber for this New England plan type was actually pre-cut prior to shipment around the Horn. It may be considered in a broad sense, therefore, a very early example of prefabrication. It also has the distinction of being one of the first wood frame houses in the islands. Architecturally, it simple and straight-forward expression, the relatively low ceilings, and basement are strong evidence of its New England concept, alien to the temperate climate of Honolulu.

Having been restored in 1935 and maintained by a dedicated group of descendants of the early missionaries for whom it was built, it stands in good condition.

DETAILED DESCRIPTION OF THE EXTERIOR

This existing house consisting of two stories plus a basement measures 40' - 3 1/2" in length and 24' - 2 1/2" in depth excluding the kitchen wing which extends the basic rectangular plan on the right rear (ewa-makai) by 20' - 1 1/2". The overall height from grade to roof peak is 23' - 7".

Foundations: The boundation wall varies from 9" to 1' - 2" in thickness, except on the left (Waikiki) side where it becomes an average of 1' - 10" and where a now demolished wing once stood. The walls are adobe brick set in a mud mortar. Reinforced concrete buttresses were built against the inner surfaces in the basement in the 1935 restoration. In addition, irregularly square piers of coral rock support interior beams. There is a display panel which exposes the adobe brick in the transverse interior bearing wall at the left (Waikiki) end of the basement.

Structural system: According to an article in the Friend, September, 1935 (see appendix A) by Mr. Dickey, Architect for the 1935 Restoration, all wood framework was replaced with termite-proof wood. The article further states that original siding, flooring, doors, window, cupboards, etc., which was retained was individually treated and re-used. Mr. Dickey also installed steel beams cased in wood to early floor loads as well as a reinforced concrete perimeter beam on the exterior walls.

The semi-round roughtly-squared timbers of the roof rafters and beams may possibly be original or re-used.

Porches, stoops, bulkheads: There are two sets of coral rock stoops on the King Street (mauka) elevation and one stoop of the same material on the rear (makai). The latter is not aligned axially with the stoop at the main entrance, but rather with a window. There is no protective roof at either.

Kawaiahao Church and Mission Houses
CONTINUATION SHEET ITEM NUMBER 7 PAGE 6

There is also a small two-story wood framed porch on the right side (ewa) of obvious latter date.

There are, in addition, coral rock bulkheads at both the front and rear, which enclose a coral rock stairs to the basement.

Early photographs in the Mission Society Library indicate there have been at least three different porches on the front (King Street).

Chimneys: The single chimney which is at the end of the kitchen wing is of coral rock and brick, plastered on the exterior with cement stucco. It is 15 feet high. The arched head of the opening is supported by two 2" wide curved iron straps, bent so horizontal legs are built into the masonry side walls of the fireplace. A hanging pot crane is also built in. The hearth is stone.

Openings - doorways and doors: The three exterior doors on the ground floor are all treated similarly with plain unmoulded trim. The two exterior doors to the basement are set into the basement walls without trim. A ventilating transom covered with wire mesh is set over these basement doors. On the King Street front (mauka), the wood door is 6-paneled; on the rear (makai), there is a 2-light transom over the 6-paneled door; the door on the porch on the east (ewa) is a dutch door of vertical boards on the exterior fastened to horizontal boards on the interior; the kitchen door is also Dutch, consisting of two wide vertical boards, braced on the interior with horizontal rails. The two basement doors are also vertical planks.

Windows and shutters: The majority of the windows are 6/6 wood double-hung, using iron pins instead of sash weights. Exceptions are a fixed six-light window on the second floor, a 6/6 sliding wood window and a six-light fixed wood window in the kitchen. The smaller window openings on the second floor have adjustable wood louvered shutters without windows.

Roof - shape, covering: The gabled roof over the main house and the kitchen are both covered with asbestos shingles.

Cornice, eaves: The cornice board is a simple flat band with a narrow moulding at the top.

Dormers: There is a wide gabled dormer with a single louvered window on the front (King Street), with the plastered ceiling on the interior being arched.

DETAILED DESCRIPTION OF THE INTERIOR

The Basement in plan consists of one room on the left (Waikiki) and a larger space on the right. The latter is divided by a stud portion and large square plastered stone piers. Access is by an exterior coral stair on both the front and rear and an interior concrete stair leading down from the kitchen. All walls are plastered, the floors are brick and the ceiling exposed wood.

The first floor plan which has been altered by both additions and demolition (on the left) consists of two rooms across the front. A smaller room and stairhall are located behind the front room on the left. The room on the left extends through the depth of the house, and connected by a doorway to the kitchen wing on the rear, and one to the covered porch on the right. The rear part of this porch has been enclosed. There is also a stairway leading from this large room up to the second floor.

The second floor consists essentially of two large rooms separated by a stair-hall. Under the eaves on each side smaller rooms have been partitioned off. In the right rear corner there is the second stairway down to the large room below.

Stairways: When the house was first enlarged, the original stair way was relocated and the second stairway in the rear right corner was added. Both stairs are ell-shaped with winders. Both are enclosed except for the wood balustrade at the head of the centrally located stair.

Flooring: The floors are brick set in earth in the basement, cement in the kitchen and random width boards in the first and second floors.

Wall and ceiling finish: Walls are plaster on adobe brick in the basement, plaster on coral rock in the kitchen and plaster on wood framing in the first and second floor. There are also two painted plank partitions on the second floor. Ceilings are exposed wood framing in the basement and kitchen and plaster in the main house.

Doorways and doors: Several types of doors are found in the house. Some are 4-panel on either one or both sides and others are 6-paneled on one side only. There is also a cased opening in the left front room. Doors in the small built-in cupboards are also paneled.

Decorative features and trim: The base boards are all flat unmoulded. Door and window trim is simple with small framing moulding. The rooms downstairs and the major rooms upstairs have narrow moulded chair rails and picture rails. Wood clock shelves are also installed.

CONTINUATION SHEET ITEM NUMBER 7 PAGE 8

Notable hardware: Door latches are of two general types: the flat door pull and thumb latch, and the more decorative spool handle with scalloped escutheon plate. There are also several sliding lock bolts surface mounted.

Lighting: None.

Heating (fireplaces): The only fireplace is the stone fireplace in the kitchen. The opening is slightly arched. A swinging pot crame is embeded in the inner rock walls.

SITE AND SURROUNDINGS

Orientation and general setting: On the south side of King Street, the Mission Frame House is on the left (Waikiki) side of the Mission Printing Office, one of the three mission buildings on the property.

Outbuildings: Adjacent in the rear is a small frame structure containing rest room facilities.

Landscaping: The three Hawaiian Mission Children's Society's buildings are set back from King Street on a grass lawn, enclosed by a low coral rock wall with iron gates.

Typical plants, trees and shrubs are informally scattered on the lawn. Some of these are the Banana tree, Royal poinciana, Pili, Ti, Hibuscus, and the Octapus tree.

Alterations: Other than changes cited above, the fundamental alterations in the building were successions of internal partitioning which were done to accommodate more inhabitants than the building was designed to house. In 1828, an addition, 15 1/2 by 17 feet was attached to the east end of the house to serve as a bedroom for the Bingham family. This addition was removed years later. In 1829 the roof was extended to provide for another upstairs room. No record of either extensive repair or alteration has been found for the period 1830-1907.

In 1904 at a meeting of the Hawaiian Mission Children's Society, also known as the Cousin's Society, it was suggested that the mission frame house be obtained as a home for the Society. In 1906 the house was sold by A. F. Cooke to C. M. Cooke, Ltd. In 1907 Mr. Charles M. Cooke offered to leased it to the HMCS for twenty years at a dollar a year with the idea that if they were interested enough to keep it in good condition it might ultimately be ceded to them as, in fact, it was in 1925. A committee was appointed to look into the condition of the house. Several contractors were called in to examine the

building which was found to be so badly eaten by insects as to be considered beyond repair. Various suggestions were made for restoration, such as an inside steel frame to hold the house up or the injection of liquid cement into the timbers, but hhe cost was prohibitive. After considerable study the HMCS committee submitted their report, recommending extensive repairs to restore the house to its original appearance. The cost of these repairs when completed was approximately $1500. The details of the renovation are contained in the HMCS Minutes of the Board of Managers meeting January 23, 1907:

> "That the building be made water right at once, and those sills and beams which, upon examination, prove to be rotten be replaced; that the partitions lately placed in the building be removed and the house restored as to its original conditions as far as possible; that the plastering be repaired; the floors renewed and the room repapered; that the roof be re-shingled with shingles dipped in oil; that the kitchen be re-slated, it now consisting partly of shingles and partly of slate, ...that all the old hardware be preserved or replaced; that window casing be put in to slide in the sills as appears to have been the original method; that all the medicine and book shelves be retained; that a new front door similar to others in the building be made and put in place; and that the exterior of the building be painted." This cost for these repairs was estimated.[4]

In 1925 when the HMCS gained title to the house, the premises were again inspected and again extensive insect damage was found. A. E. Arledge, who inspected the house, advised that the first floor was unsafe for more than six people in any one room or concentrated location, but it could easily be strengthened by studding and shoring without removing any of the old timber. This would make the house safe for three to four years and cost about $150. But Arledge urged that permanent repairs be considered. It was another ten years, however, before funds could be raised for a complete restoration, but the need had been seen and several plans were discussed in the meantime. In April 1930, C. W. Dickey, Architect, submitted specifications for constructing an inner concrete shell around which the original wood frame and interior could be placed. Dickey estimated the cost at about $6900, but pointed out that this would be fireproof, insured against insect damage, and the original

CONTINUATION SHEET ITEM NUMBER 7 PAGE 10

exterior appearance of the house would be retained. This plan was not approved, however, for it was felt that the concrete shell would make the walls too thick and destroy the original proportions of the house.

By 1935 the HMCS was able to procure sufficient funds to completely renovate and restore the frame house. C. W. Dickey was again consulted and his specifications for the work were submitted in September 1934. His plan was to retain the original thickness of the walls, partitions, and floors as well as original clapboards, doors, windows, cupboards, and shutters, but to replace the wood framework with termite-proof lumber. Detailed photographs of every room were taken before the work started. As a result, the house looks exactly as it did before, both inside and out, but it is strong and well built.

Since 1935 various minor repairs such as repainting and some replastering have been undertaken. Today the old mission frame house is maintained by the Hawaiian Mission Children's Society as a memorial to the early missionary effort in the Hawaiian Islands. Momentoes and furniture of the first mission families are displayed in the house, together with photographs of the men and women who lived and worked there.[5]

Adobe Schoolhouse:[6]

General: The building has good, simple lines. Today, it is a unique example of Hawaiian adobe wall construction.

Condition of Fabric: Generally good. Original thatch roof long gone; roof line was probably lowered when shingles were substituted. All woodwork seems to be modern.

EXTERIOR

Number of Stories: One.

Shape: Original outline a simple rectangle; new (c. 1965) wooden addition at rear slightly wider.

[5]More detail, including footnotes and specific data on the alterations, is contained in the HABS file which is included here by reference.

[6]Description of the schoolhouse is taken from the Data Sheets filed with HABS, File HA-19, "Adobe Schoolhouse," prepared by Charles E. Peterson, FAIA, September, 1967.

Kawaiahao Church and Mission Houses
CONTINUATION SHEET ITEM NUMBER 7 PAGE 11

Overall Dimensions: 30' - 8" x 54' - 9 1/2".

Foundations: Not revealed.

Walls: Indoors, a panel opens to reveal original adobes 6" wall height and 1' - 6" long. The wall thickness is (plaster face to plaster face) 2' - 9".

Finish: Rough sand plaster, tan color. A hole in outside plaster reveals that it was applied to wire lath with an air space outside of adobe blocks.

Front Stoop: A low concrete stoop at front door.

Chimneys: None.

Front door: Modern double door hung in a light wooden frame.

Windows: Wooden double-hung sash of 8" x 10" lights, 9/6. The frames are set in recesses with arched heads - inside and out. Masonry sills seem to be of concrete. Modern wire insect screens hung from top.

Roof: Low hip roof covered with wood shingles.

Cornice: Shallow box cornice with plaster soffit and screened vents.

INTERIOR

Floor Plan: The original adobe section is in one room. A kitchen and small meeting room occupy the rear modern addition.

Stairways: None.

Flooring: Concrete.

Walls and Ceilings: Inside plaster wall appears to be furred out about 4" from adobe walls. Ceiling height: 10' - 10". No trim except low concrete baseboard.

Miscellaneous: No decorative features, hardware or lighting fixtures of interest. No heating arrangements.

Kawaiahao Church and Mission Houses
CONTINUATION SHEET ITEM NUMBER 7 PAGE 12

SITE AND SURROUNDINGS

Orientation: Normal to King Street.

Outbuildings: None.

Landscaping: No enclosures. Simple landscape plantings of recent date. Building open to street on one side and to the Kawaiahao church grounds on the other.

Alterations:[7] The Old Mission Schoolhouse, as this adobe building is also known, was first used for the mission's General Meeting of April, 1835. It had been built over the preceding two years, as adobe bricks, lumber and time were available, to replace an earlier straw school and meeting house on the same site. The new building was 24 x 40 feet inside, with walls 12 feet high and 30 inches thick, built in two tiers of brick with a space between. Each long side had four deeply recessed windows; there was a single window at the back end (later made into another door) and a wide double door with two windows facing on the street side. The adobe blocks were covered with clay plaster and lime whitewash, patted on by hand so the palm and finger marks showed. There was no floor or ceiling, and the roof was pili-grass thatch. The same furnishings served for both school and meetings: unpainted soft pine benches about 8 feet long, with a sloping desk attached to the back and a shelf below for books and slates. The soft pine was especially tempting for young whittlers. These benches, with a central aisle, filled most of the room; a long bench ran across the far wall and a table for the teacher or meeting chairman occupied a space between. The whole had cost approximately $700, mostly in donations, including gifts from King Kamehameha III and his adopted son, Alexander Liholiho (Kamehameha IV), who attended the official dedication in 1836.

By 1920, the building was a bad repair, with a roof almost gone and the woodwork termite-ridden. As part of the Mission Centennial that year, the HMCS, which had leased the property from Kawaiahao Church, had the building repaired and restored. The work included a lath and plaster shell over the old adobe walls, with a flat cement stucco outside finish. A concrete floor with wooden covering and a wooden ceiling were installed. The repaired building was then leased to the Free Kindergarten and Children's Aid Association for use as their headquarters. Over the years the Kindergarten Association made other changes,

[7]History of modifications taken from Data Sheets (HABS), File HA-19, "Adobe Schoolhouse," by Frances Jackson, September 1966.

(CONTINUED)

GPO 892 455

including electricity, plumbing and general repairs and obtained a new lease direct from Kawaiahao Church. This lease arrangement lasted until 1961 when the church found it necessary to retain the building for its own use.

In the 1940's, the building underwent a second rehabilitation when it was found termites had badly destroyed the woodwork of the 1920 restoration. The walls were reinforced with steel lath and again the inner and outer walls were plastered with stucco. The roof was rebuilt and extended, and reshingled with fireproof asbestos shingles. (Shingles are now wood on a light frame; no sheathing to indicate possible asbestos shingles.)

In 1966 the building is standing idle. There are plans for properly restoring the Old Mission Schoolhouse as part of the Kawaiahao Church and Mission Historical Houses National Historical Landmarks. It is the only remaining building in Honolulu with all four walls built of adobe bricks. The building is used as a meeting room for the smaller church groups. Plans schedule restoration for 1979.

Chamberlain House:[8] The simple form of the building, with cellar, two stories and an attic, is similar to houses of the same period in New England. The massive exterior walls are built of coral blocks set in lime mortar.

SITE

The house is prominently located, set back from the streets on an irregularly shaped tract approximately 1.1 acre in size. Other buildings on the site include the wood Frame House, the First Printing House and the recently-constructed Mission-Historical Library. On the property line adjacent to the streets there is a three-foot wall of coral stone.

EXTERIOR

Overall Dimensions: The two-story major portion is 26' - 8" by 54' - 9" with a rear two-story wing 16' - 6" by 22' - 2" in size.

Foundations: Basement and foundation walls and intermediate piers are of coral stone, rough, unplastered.

[8]Description taken from the Data Sheets, HABS HA-4, "Chamberlain House."

(CONTINUED)

Wall Construction: Thick masonry exterior walls are of coral stone surfaced with an exterior cement plaster finish simulating stone with wide joints. Exterior gables are finished with siding, now asbestos, probably originally wood siding.

Porch, etc.: On the south corner adjacent to the kitchen there is a one-story porch and a latticed enclosure.

Chimney: The chimney flue is within the wall of the kitchen. Above the roof the chimney is built of brick.

Doorways and Doors: Steps and stoops at entrance doors are of coral stone. Exterior doors are deeply recessed. Two glazed window-doors in the cellar provided access for supplies through the light wells.

Windows: Small windows in the cellar are barred, no glazing. Windows on the first and second floors are double-hung wood sash.

Roofs: The main portion and the rear wing are ridge roofed with gables. The present roofing is composition shingle over wood sheathing.

Alterations: A detailed account of the structural history of the building has not been located. Hussey reported in 1962 that in 1919 the house was "completely renovated" but apparently little altered.[9] A detailed description of the interior of the house as of 1895 is contained in the HABS file. It was carried by the Pacific Commercial Advertiser on March 9, 1895.[10]

Print Shop:[11] The Mission Printing Office represents a purely utilitarian structure, built to house the first printing press in Hawaii.

[9]John A. Hussey, NSHSB form "Mission Houses," July 19, 1962. A report by Frost and Frost was recently (8/29/78) indicated to be filed in the Hawaii Mission Children's Society Library, Honolulu. This report, it is said, discusses the changes.

[10]HABS file HA-4 also contains photos of the house taken July 1966 and photocopies of early prints and sketches.

[11]Description taken from HABS Data Sheets, "Mission Printing House," prepared by Woodrow W. Wilkins, August, 1967, in the file HA-20. That file also contains photographs taken in July 1966 by Jack E. Boucher and field notes by R. K. Yomomoto and Ron Saiki, July 10, 1967.

(CONTINUED)

Condition of Fabric: Although there has been some efforts in the recent past to stabilize the structure, there seems to be serious progressive deterioration of interior plaster and exterior mortar. Both are rapidly drying out to the point of pulverized powder. The building was restored by Frost and Frost. Exterior coral was painted. There was a considerable amount of efflorescence on the interior walls at the time. Now appreciably improved since the repainting. Gutters were added and new roof installed.

DETAILED DESCRIPTION OF EXTERIOR

This is a simple one story rectangular building measuring 29' - 10" x 18' - 8", excluding 5' - 1" porch (lanai).

Foundations: Not accessible but presumed to be coral rock similar to the bearing walls.

Wall construction, finish, color: Walls on the King Street (mauka) and right (ewa) sides consist of natural coral rock in random sizes set in heavy mortar joints which average 3" - 4" thick in the horizontal and 4" - 8" wideve vertically. The rear (makai) and left (Waikiki) walls are finished smooth in modern white cement stucco over the coral rock. (In 1978 this is no longer true.) Coursing on the front wall is more regular than on the ewa wall. (1978 the wall is exposed coral rock with paint on the exterior.)

Structural system, framing: The modern roof is framed with 3" x 4" roof rafters, 3' - 0" o.c. with 3" x 3" purlins, irregularly spaced, which carry the galvanized corrugated roofing directly. Diagonal and vertical braces are 1" x 4".

Porches, stoops: A continuous lanai (porch) extends along the King Street (mauka) side of the building, roofed by a continuation of the main roof slope, and supported on the edge by four 4" x 4" posts. Early photographs (1889) show several more posts in a different bay arrangement, and also the fact that the porch was extended to connect to the Mission Frame House on the left. These photographs also indicate a wood floor, since replaced by smooth finished concrete. There are two coral rock steps from grade in the center. On the rear (makai) side a detached shed roof covers a modern concrete walk with a coral block stoop up to finished floor level. (In 1978 this feature is no longer present.)

Chimneys: None.

(CONTINUED)

Openings - doorways and doors: On the front (mauka) there are two doorways - one in the center and one to the right (ewa). It is quite possible that this latter doorway was originally a window. A timber lintel is set in the stone work over the openings. Door trim, flat jamb and head, is set flush with the stone wall and is obviously of recent installation. There is no sill at the cement step up to floor level. Within the full width of the opening above the door there is an open wire covered ventilator 6 3/8" high. A similar doorway is in the center of the rear (Makai) wall. All doors are 6-panel wood, 1 1/4" thick with horizontal rails tennoned into stiles.

Windows and shutter: The window sash are wood double hung with iron pegs instead of sash weights to control opening. On the front there are 12/8 lights of 8" x 10" glass, and on the rear 6/6 lights with 7" x 9" glass. The exterior wood sills are let into the stonework similar to the head. The sills on the interior are concrete.

There are no shutters although the 1889 photographs shows shutters at the central doorway and also at the window to its left. There remains two bracket pintles in the right jamb of this window. (In 1978 building shows wood louvers in the gabled ends.)

Roof - shape, covering: The gabled roof is presently covered with galvanized corrugated iron which appears also in a 1915 photograph. A 1906 photograph shows a shingle roof which may be wood or slate, therefore the present roofing material dates between the 1906 - 1915 period. (Re-roofed in 1965.)

Cornice: A flat 6" fascia serves as a cornice on the gabled ends.

DETAILED DESCRIPTION OF THE INTERIOR

Floor plan: The interior consists of two rooms, each having a cupboard built into the stone walls. The dividing partition also contains a cupboard framed together with the doorway. A recent exploratory dig near the doorway discloses a new 4" x 4 5/8" lintel over the doorway, a recent replacement. It has not been possible to determine whether this coral partition is original or a later addition.

Stairways: None.

Flooring: Modern smooth finished concrete.

Kawaiahao Church and Mission Houses
CONTINUATION SHEET ITEM NUMBER 7 PAGE 17

Wall and ceiling finish: The walls and ceilings are white plaster which is 1" thick at the exploratory holes. Plaster is finished up to the wood trim at the openings.

Doorways and doors: The single doorway and cupboard are framed into one large opening in the room on the right (ewa). The jamb and head trim is modern. The door has been removed.

Decorative features and trim: There are no decorative features. The exterior angle at the intersection of the plastered reveal and the wall is covered by a moulded wood trim piece.

Notable hardware: None.

Lighting: Modern electric.

Heating: None.

SITE AND SURROUNDINGS

Orientation and general setting: On the south side of King Street, the Printing Office is closely set between the Mission Frame House on its left (Waikiki) and the Chamberlain House on its right (ewa).

Out buildings: None.

Landscaping: The three Hawaiian Mission Children Society's buildings are set back from the street on a grass lawn, enclosed by a low coral rock wall with iron gates.

Typical plants, trees and shrubs are informally scattered on the lawn. Some of these are the Banana tree, Royal poinciana, Pili, Ti, Hibiscus and the Octapus tree. Coral stepping stones are set in the lawn.

Alterations:[12] Between the two mission houses on land given by King Kamehameha II to the first mission company as a homesite, stands the old Mission Printing House. Constructed in 1823, it is reputed to be the first printing house west of the Rocky Mountains.

[12]The structural history of the building is taken from Karmen Tiahrt, Data Sheets, August, 1967, HABS file HA-20.

Kawaiahao Church and Mission Houses
CONTINUATION SHEET ITEM NUMBER 7 PAGE 18

The pioneer Mission company to the Hawaiian Islands brought their Ramage printing press around the Horn in 1820 and when it was unpacked in Honolulu in August of that year, it was found to be undamaged. Temporarily the press was housed in a thatched house belonging to the Mission family. However, when wind blew the roof of the hut off, the press was taken into the home of the Loomis family where it was again set up. There on January 7, 1822, the first public printing was done on the press with Governor Keeaumoku taking off the first sheet. Printing was continued for several days in February 1822, but operations were then suspended until a permanent home for the press could be provided.

By the end of December 1822 construction of a printing house was underway. The work was done by members of the Mission company stationed in Honolulu with, no doubt, some native assistance. Some sources credit Daniel Chamberlain as chief builder of the printing house as he had begun the construction. However, Chamberlain left Hawaii in March 1823 and other men, particularly Elisha Loomis, who was in charge of the press, and Levi Chamberlain, who arrived in April 1823, seem to have taken charge of the work. As there was a distinct "want of beams, plank, boards, and shingles," it was decided to use coral stone for the building material. The coral was easily obtained in abundance near the vicinity of the mission houses at a depth of a few feet from the surfact of the ground. The coral was "laid in mortar of the common soil." Fortunately, the mission was able to purchase the hull, bowsprit and two masts of the wrecked whaling ship Ruby to use in building the printing house, a dwelling house and for fuel. By August 1823, the Mission could report that they had "Completed the walls of the printing house which when covered will be ready for use. The building has cost 250 dols, and will probably require 50 more to complete it ... the dimensions are 28 feet by 17 which will afford room for two presses with their variety of apparatus."

It had originally been proposed to make the building fireproof by covering it with tile ordered from Canton. However, the decision hinged on two considerations - if the tiles could be procured at a reasonable cost and if a person could be found who understood fitting them on. By the end of August 1823 the decision had been made and tiles from Canton had been ordered to cover the roof. There is, however, no record that such tiles were actually received or used. At the same time glazed windows for the printing house were requested from the Mission Board in Boston.

By November the building was nearly complete and shingling of the roof was begun on November 5. The mission report noted that "we are obliged to make our shingles in part of bits of thin boards rived and hewed with a hatchet by the natives of the Northwest coast." Elisha Loomis, however, records that the mission had to saw their own boards and split the shingles.

Kawaiahao Church and Mission Houses
CONTINUATION SHEET ITEM NUMBER 7 PAGE 19

The roof was finished in about three weeks, by November 22. The inside walls were quickly covered with tapa pasted on with poi. Perhaps this did not prove very satisfactory, for less then a year later, Mr. Loomis was investigating the possibility of laying over the inside of the printing house with plaster made of "lime and a peculiar kind of clay called pohu found near the Pearl River.

By December 2, 1825, the printing house was complete and Mr. Loomis moved in and set up the press. A few days later he began printing an edition of Hawaiian hymns.

It would appear that even this printing house did not prove satisfactory for long. Two years later on December 26, 1825, Mr. Loomis wrote to the Mission Board that "our present printing office being much too small, we have commenced building an addition to it of some 30 x 19 feet and two stories high." The building referred to by Loomis may, however, have been built across the street, rather than as an addition to the original printing house as there is no other confirmation of such an addition being constructed.

After 1825 there is an almost total lack of records concerning the mission printing house, and any repairs or alterations made to it. It appears that it was used for twelve years by the Mission printers and was then associated with the frame house standing just adjacent on the Waikiki (left) side of the building. In a letter of November 14, 1844, from Levi Chamberlain to the Mission Board, he speaks of the building as serving both as a storehouse and a dwelling, being united to the frame house by low buildings. According to the remembrance of a member of the Hall family in 1907, her parents, the Halls, lived in this building and she was born there in 1842. In 1851 the printing house together with the frame house came into the possession of the Cooke family. It is not known what use they made of the building, but as they kept several boarders in their home, it is possible they may have used it for their accommodation. According to a friend of the Cooke family, Mrs. A. S. Cooke continued to live in the buildings until 1880 and for perhaps eight years after this it was occupied by other family members and friends. It then stood unoccupied for several years.

Interest in preserving the frame house as a relic of the early mission days in Hawaii led to the acquisition of this building together with the printing House in 1907 by the Cousins Society, officially known today as the Hawaiian Mission Children's Society. Mr. Charles M. Cooke had offered to lease the buildings to the Cousins for a dollar a year with the idea that if they were interested enough to keep them in good condition, they might ultimately be ceded to them as, in fact, they were in 1925.

Kawaiahao Church and Mission Houses
CONTINUATION SHEET ITEM NUMBER 7 PAGE 20

The HMCS committee appointed to investigate the condition of the mission buildings found the printing house to need few alterations. "Your committee believes that this building with comparatively little expenditure can be made almost fireproof by the building of a new roof of slate instead of shingles and with all the supporting timbers covered with tin. (later on in the rear of this building, a fireproof vault can be built.) The total cost of this work will be in the neighborhood of $2750." This cost estimate seems to include $15000 needed for the frame house. There are no records to indicate that the alterations recommended by the committee were completely carried out.

After its renovation the printing house became the office of the HMCS in 1908 and served in this capacity until 1950. Apparently before the Society moved in, a cement floor was laid and shelves were built to hold the reports and papers of the group. The walls were also freshly cemented and plastered and the building was considered to be insect-proof.

The only records concerning repairs and laterations to the printing house in the ensuing years are for minor work such as painting, replastering and repairs for insect damage. The printing house today is used as a museum; a replica of the first printint press and its print work are displayed in the building along with other memntos from the early mission family.

Mission Cemetery: The cemetery is located between the Kawaiahao Church and Kawaiahao Street. Because of its association with the church and mission it is included in the landmark as a contributory element.

King Lunalilo's Tomb:[13] This small mausoleum was erected according to the will of King Lunalilo to house his remains. Its architectural merit is two-fold. Besides being one of the few Gothic Revival structures on the island of Oahu, it is one of the earliest constructions in concrete block in America.

Condition of fabric: Although structurally sound, peeling paint and pitting off the exterior finish is visable. On the interior, there is evidence of a leak in the upper left (Waikiki-makai) corner.

DETAILED DESCRIPTION OF THE EXTERIOR

The single-story building has a cruciform plan with an exterior porch extending beyond the entrance towards King Street (the mauka side). The over-all exterior

[13]Description is taken from HABS Data Sheets, file HA-15, prepared by Woodrow W. Wilkins, June 5-7, 1967.

Kawaiahao Church and Mission Houses
CONTINUATION SHEET ITEM NUMBER 7 PAGE 21

dimensions are 23' - 0 1/2" x 23' - 0 1/2", excluding the angle buttresses and entrance porch. The latter measures 9' - 2 1/2" wide and 9' - 10" deep. The exterior height measures 28' - 4 1/2" from the ground to the top of the coping at the peak of the gable, excluding the concrete cross which si an additional 1' - 9 1/2" high. The interior floor to ceiling heigh- is 22' - 11 1/2".

Foundations: Although a small portion of the concrete foundation wall is visible, the depth and width are not accessible.

Wall Construction: The exterior bearing walls are constructed of concrete blocks, measuring 1' - 0" high by 3' - 6" to 3' - 8" long. The face to face wall thickness is 1' - 4". The wall rises from a base with wash. This base consists of 2 courses for an overall height of 3' - 0", projecting 3 1/4" beyond the face of the wall. The wall is further articulated by a moulded string course which is a continuous extension of the moulding at the imposts of the lancet arches on the entrance porch. The walls are extended at each exterior angle to form buttresses 1' - 6" wide with a 1' - 4" projection. These buttresses terminate in a double wash 13' -3" above grade. The gable walls are extended 9 1/2" above the roof ridge by a coping, surmounted at each peak with a concrete cross of modified Avillon design, 1' - 9 1/2" square. At the lower end of the rakes, the coping from LABEL-STOPS with small bracketed gables. There are moulded roundels, 2' - 6 1/2" in diameter high in the center of each gable. The roundels are solid except for quatrefoil openings, 5" across, which are open except for wire screening for ventilation.

All exterior wall surfaces are finished in smooth light buff-colored stucco with both vertical and horizontal joints visible.

Structural system, framing: Existing roof framing behind the existing plaster ceiling is not accessible. The gardener, in service for approximately 20 years, states that he remembers when the ceiling was exposed wood resting on timber trusses. It is quite probable that the earlier framing was modeled after that of the Royal Mausoleum, constructed by a German architect, Theodore C. Heuck, in 1863. Concerning this building (the Royal Mausoleum), we are told that "the roof timbers from the four wings formed a dome over the center hall." Timber trusses were definitely used on the exterior porch of Lunalilo's Tomb.

Porches: The entrance porch (mauka side), with pointed arched openings on three sides rises 24'-2 1/2" from the ground to the peak of the gabled coping, excluding the cross. The floor finish is concrete. The existing ceiling is modern concrete, replacing modified hammer beam trusses. Evidence of these trusses is found on the face of the entrance wall of the main structure. The approximate dimensions were ascertained. The hammer brace extended out 2'-0" from the interior face of the wall. There was a horizontal spanning member

6" deep, which is turn supported an arched collar brace of undetermined dimensions, springing from the end of the hammer brace. The rafter was 8" deep. On the side walls, 2" x 12" pockets, now filled in, were spaced 2'-1" at the intersection of the roof and the wall.

The porch floor is extended on all three open sides 2'-0" beyond the face of the piers, from which concrete finished steps lead to grade. These steps consist of 5 risers at 7 1/2" and 4 treads at 1'-3" including the moulded nosing.

Openings: The single doorway opening consists of a Gothic lancet arch with a hood moulding. The double in-swinging flush wood doors, varnished, are 2 1/4" hung on 3 brass butts. Applied in relief on each of the doors is the royal crown, executed in wood. Two iron grille gates filling the opening are set on the exterior face of the jamb. The principal vertical and horizontal members are 1 1/2" square and the intermediate vertical rods are 3/4" in diameter, spaced 2 3/8" o.c. There is a single vertical locking bolt with recessed keepers in the center at the head and concrete sill, the latter being 1 1/2" above the interior floor. Each gate is hung on a single pintle embedded in the jamb, and a pivot embedded in the sill.

Two lancet windows are centered on the remaining three faces of the building. The interior wall opening is 1'-3" wide and 6'-1 1/2" high. The width of the opening on the exterior is 1'-8 1/2". The two window openings are united by a pattern formed of quoins with an over-all width of 5'-6". Individual hood mouldings occur over each window. The sills and jambs of the reveal are splayed on the exterior while the jambs only are splayed on the interior. The wood window frames consist of 2 3/4" sill, 1 1/2" jamb and 2 1/4" vertical distance at the head, with an over-all width of 11 1/2". There are 6 diamond-shaped panes arranged vertically 10 1/2" o.c. in the center of each window, flanked by half-diamond lights on each side. At the head of the lancet is a single trefoil light. Three of the six windows are of etched yellow stained glass which are probably original. The remaining three are glazed in modern patterned glass.

Roof: Four intersecting gables cover the main structure. The porch also has a gabled roof, the ridge of which is 23'-0" above grade. All Roofs are covered with modern asbestos shingles. A modern galvanized metal ventilator has been installed on the slope on the left (Waikiki) side of the entrance wing. There are no cornices, dormers or towers.

DETAILED DESCRIPTION OF THE INTERIOR

The floor plan is laid out as a single centralized cruciform space with the existing ceiling following the slopes of the four gabled roofs.

CONTINUATION SHEET ITEM NUMBER 7 PAGE 23

There are no stairways.

The cement underfloor is covered, wall to wall, with a modern red carpet.

Walls and ceilings are finished in smooth white plaster, relieved only by the varnished wood of the simply moulded door trim which is 7" wide and flush with the plaster. There is no wood trim at the window openings which have a 6 3/4" interior reveals.

The sole decorative features of the interior are the three royal standards (kahilis) set in wood table-like stands. The kahilis are executed in red and black feathers and cloth with one at the head of Lunalilo's Tomb and one on each side in the makai arm of the cross.

Lunalilo's Tomb consists of a simple highly polished white marble sarcophagus centered under the crossing. It is 8'-1" x 3'-1 1/2" x 3'-6" (including the 6" vert antique base). The top slab extends 1" on all sides. Read from the right (ewa) side, the name, "Lunalilo," is incised in letters 11" high and 57" long. These are centered. The front (mauka) end panel contains a carved royal crown.

Separated 3'-1 1/2" on the right (ewa) side is the tomb of Charles Kanaina, an exact duplicate of Lunalilo's except that the incised name, "Kanaina," 4" high and 22 1/2" long, begins 4" from the edge nearest the entrance rather then being centered.

There is no notable hardware, artificial lighting nor heating system.

SITE AND SURROUNDINGS

Located in the Honolulu Civic Center in downtown Honolulu, the mausoleum is on the roughly south-east (Waikiki-makai) corner of the intersection of King and Punchbowl streets. It is oriented in a north northeast direction, the entrance facing King Street.

It is enclosed separately within the enclosing walls of Kawaiahao Church (1842) grave yard, the makai-ewa wall common to both. This wall is coral rock stuccoed, 6'-2 1/2" high to the crown of the coping. Enclosure of the other two sides of the tomb grounds is made by a stuccoed wall 2'-0" high, surmounted with a decorative cast and wrought iron fence, 6'-3", over-all height. Enriched intermediate posts are 6'-7 1/2" high. On the outside of this iron fence is the paved carriage way to the Church. On the axis of the tomb entrance a double carriage way gate, flanked by pedestrian gates, leads to a circular carriage way before the tomb. This carriage way is paved with

coral rock set in cement.

Located 10'-6" away from the walls of the mausoleum are 8 free-standing pedestals, 3 on each side and 2 on the rear, symbolic of the 8 islands. These pedestals are 4'-10 1/2" high, having a 1'-6" square base. The shaft, 1'-0" square, contains decorative panels. The base and the capstone are moulded.

The entire enclosure is landscaped with grass and a large variety of tropical plants and trees. These include the following: Maile scented fern (lauae), Ti, Royal poinciana, Monkey pod tree, Golden shower tree, Native fan palm (loulu), Coconut palm, Golden fruited palm, Queen sago palm, Croton, Plumeria, Pothos vine, Star jasmine, Alexandrian laurel (kamini), Shell ginger, Octapus tree (brassaia) and Guava tree.

site of the present church. This structure was "the first house consecrated for the worship of God in the Sandwich Islands." It burned in 1824, and Chief Kalanimoku, the prime minister of the Hawaiian kingdom, ordered another built at public expense. It stood near the site of the first and was built of wood, measuring 70 by 25 feet. Upon his return to Honolulu after surpressing a rebellion on Kauai, Kalanimoku early in 1825 ordered a public ceremony of thanksgiving held in this chapel. Apparently this was the first of a long series of public meetings held at Kawaiahao Church. Funeral services for King Liholiho and Queen Kamamalu, who had died in England, were also held in the chapel. To accommodate increasingly large congregations, which sometimes numbered 3,000, a large temporary chapel was built in 1825, but it was soon destroyed by a storm. It was followed by a third meetinghouse, built in 1827, and by a fourth, erected in 1828-1829, the last being a high thatched building, 196 by 63 feet.

In 1833 services in English only began to be held at a building nearby, and Kawaiahao "became more distinctly a Hawaiian congregation." A permanent white congregation was formed in 1837, and the next year a second native church was formed.

At the instance of King Kamehameha III, a long-planned stone church was begun in 1836. The task of constructing a stone building 144 feet long and 78 feet wide was a huge one for the time and place; and the funds to purchase needed lumber and materials from Boston were raised by public subscription. During 1837 the work of gathering local materials--almost 14,000 coral rocks, timber, and lime--was started. The cornerstone was laid on June 8, 1839; but Hiram Bingham, pastor and architect of the new church, was forced by ill health to leave before the building was completed. It remained for the Rev. Richard Armstrong to preside over the dedication on July 21, 1842. King Kamehameha III participated in the ceremony and gave the church lands to the membership. From its dedication until the present day Kawaiahao has remained an active church, and it is still considered "the center of worship for the Hawaiian race."

The structure also served as the scene for a number of important state events, and it was for a number of years the place of the annual meetings of the American mission. Here in 1843 King Kamehameha III held a thanksgiving ceremony after the restoration of Hawaiian rule by Admiral Thomas, on which occasion he is said to have spoken the words which became Hawaii's motto. The legislative assembly of 1848 was convened in the church. Here Kamehameha IV and King Lunalilo were formally "inaugurated"; and here met the unfortunate constitutional convention of 1864. In this building Kamehameha IV married Emma Rooke in 1856; and here lay in state the bodies of Kamehameha III, Queen Emma, Princess Kaiulani, Queen Liliuokalani, and many other notables of the Hawaiian kingdom.

Kawaiahao Church and Mission Houses
CONTINUATION SHEET ITEM NUMBER 8 PAGE 3

The building has had several changes in name. At first called Stone Church, Honolulu First Church, or the King's Chapel, the name Kawaiahao church came into formal usage in 1862. The church is still very active and continues to carry out its historic functions as a religious center for the Hawaiian people. Services are conducted in both English and Hawaiian.

Three Old Mission Houses:[2] These three buildings, together with the nearby Kawaiahao Church, form the most important and impressive single physical monument to the work of the Hawaiian Mission, sent to Hawaii by the American Board of Commissioners for Foreign Missions, a Protestant organization supported by the Congregational, Presbyterian, and several other churches. For about 40 years after 1820 the Protestant missionaries probably were the most important force in Hawaiian politics, economics, religion, education, and social customs. The missionaries found the native Hawaiian culture disintegrating after the abolition of the old kapus and under the impact of European technology. They provided a new set of ideals and standards around which the natives could orient their lives. They found the native population decimated by European diseases and vices. They introduced medicine and attempted to regulate morals. They became advisers to royalty and brought law and democracy into the government to replace feudal autocracy and royal whim, helped keep the islands free of European entanglements, and strengthened economic and political ties with the United States. They found the Hawaiians illiterate and taught most of the population to read and write; they introduced ideals of universal education which still persist. They attempted to teach the natives the mechanical techniques of Western culture and introduced new agricultural methods and crops in the hope of creating a population of independent freeholders. The total impact of these efforts was tremendous, and the effects are apparent to this day. Even after the power of the missionaries was reduced, they and their families were an important factor in the group of foreigners who came to dominate the economic and political life of the islands.

The center of all this effort was in the Mission Houses in Honolulu, which in effect were the island headquarters of the Hawaiian Mission. Here was the source of that driving zeal and idealism which have helped mold the modern Hawaii. The significance of these structures has been well stated by Bradford Smith, who wrote in 1956: "In the heart of Honolulu, surrounded by a coral wall, the old mission houses still stand--the old white clapboard house where Bingham lived, the little coral print shop, the thick-walled coral house Levi Chamberlain built. Past them streams the modern traffic of a busy city. But they are still there in the heart of it all. And so are Bingham and Richards, and Judd and Armstrong, and all the rest--forevermore."

Kawaiahao Church and Mission Houses
CONTINUATION SHEET ITEM NUMBER 8 PAGE 4

The stories of the individual buildings are as follows:

Oldest Frame House. When the first company of missionaries prepared to leave New England for Hawaii in 1819, a Boston shipping firm donated an entire frame house, dissassembled, to be erected in the islands "for the comfort of the ladies." There being no room on the first vessel, the Thaddeus, the house did not reach Honolulu until Christmas day, 1820, by which time the missionaries at that place had spent nearly 8 uncomfortable months in thatched houses. Unloaded from the Tartar, the house was erected only after some delay, occasioned by the need for obtaining royal permission to erect a house larger than the king's. The carpenter work was performed by the missionaries themselves. During August, 1821, the Levi Chamberlain family moved into the one room then completed. The attached kitchen was not built until 1823, and the exterior clapboarding was also a later improvement.

This building was not, as is frequently stated, the first frame house to be erected in the islands, since several chiefs had bought similar dwellings from traders, but at the time "it was the most impressive." The house sheltered a number of mission families, including, until 1840, that of Hiram Bingham, the firm and stubborn, but able, leading spirit of the mission during its first 2 decades. "Through him," it has been said, "the New England mind pressed its qualities so strongly upon Hawaii that other possibilities came to seem alien."

Lucy Thurston, a missionary wife who was among the first residents in the house, has left a record of her joy at being able to move into a structure which had doors that could be shut against the ever-present curious natives. The cheerful wallpaper--pink, with vines of tinsel--was the gift of a sea captain and was stuck on with pol.

The house was sold by the mission to the Cooke family in 1851, and in 1925 it was deeded to the Mission Children's Society. One of the latest of several restorations was carried out in 1935, at which time the framework was replaced. The building was restored in 1968.

First Printing House. Even before the first missionaries left Boston, they realized that the success of their work would be largely dependent upon their being able to spread their religious message through the printed word. They brought with them on the Thaddeus a battered, second-hand Ramage press and a young printer, Elisha Loomis. Since Loomis was kept busy with carpentry and other duties, it was January 7, 1822, before the first printing was done in a grass house in Honolulu. This earliest printing in the "North Pacific region" was a vast impetus to the spread of education among the Hawaiian people.

In December, 1822, Daniel Chamberlain began construction of a more permanent print shop. The walls were of coral blocks cut nearby and cemented with common soil. The small shop, 28 by 17 feet, was completed in December, 1823, and saw "the genesis of the important printing industry" of present-day Hawaii. An early product was a 60-page hymnal; and before the end of 1824 Loomis produced the first commercial printing product--some blank bills of lading. By about 1828 the printing work of the mission had increased so enormously that the press was moved to larger quarters across the street. The coral shop was thereafter used as an adjunct of the frame house and changed ownership with it.

This Printing House is the oldest surviving structure to be associated with the Hawaiian Mission press, which exerted such an important influence upon island history. Largely due to its products, the Hawaiian people in a remarkably short time came to possess one of the highest rates of literacy in the world.

The Chamberlain House. Levi Chamberlain, described as a man who "never demanded as much of others as he asked of himself," came to Honolulu in 1823 as business agent for the mission. It was his task to store the food, clothing, furniture, and other supplies needed by all the island stations and to distribute them as required. Grass houses proved inefficient and costly for warehouse use, and in 1830 he started to build a two-story, coral-stone structure, with cellar and attic. When the building was completed in December, 1831, he moved his family into 3 rooms on the lower floor. The rest of the house was used to store the mission property. The pulley and door used to raise the boxes and barrels to the second story are still in place.

Long in ill health, Chamberlain called his family about his bed one day in 1849 and said to his wife, "Farewell. Very pleasantly have we lived together for twenty-one years. Now we must separate. I commit you to the Lord." Then this man, who more than any other had kept the fiscal affairs of the mission in good order, fell asleep and died with "not a wrinkle in his forehead." The Chamberlain family continued to live in the house and, later, acquired ownership. It became the property of the Mission Children's Society in 1910.

The Adobe Schoolhouse.[3] The Adobe Schoolhouse was constructed during the period 1833?1835, of air-dried adobe bricks and lumber, as it became available, to replace the earlier straw school and meeting house.

Kawaiahao Church and Mission Houses
CONTINUATION SHEET ITEM NUMBER 8 PAGE 6

The "most beautiful room in Honolulu," as architects have called it, was used for a school, for the annual spring General Meeting of the Mission, as a social hall, and, in 1855, as the scene of a wedding between two mission "cousins." In 1852, it saw the establishment of the Hawaiian Mission Children's Society, often known as the Cousins Society, a group of missionary descendents whose parents had long called each other "brother" and "sister."

For a while during the 1870's, the building was rented to the Government for use as a public school, at which time a partition was put in. Later, it housed the Thursday daytime meetings of Kawaiahao Church and became known as Hale Posha, the Thursday House of Kawaiahao.

The building's specific significance rests with its historic association with the mission complex expressed by its use as the educational center of the missionary operation.

King Lunalilo's Tomb. King Lunalilo's tomb, one of the early concrete block buildings in Hawaii, was built at the direction of Lunalilo's will. Apparently because of disagreement with a rival branch of the royal family, Lunalilo chose to be buried in Kawaiahao Churchyard rather than the Royal Mausoleum.

Its association with the Kawaiahao Church justifies in inclusion within the landmark.

Historical information on the Tomb:[4]

A disagreement between rival branches of the royal family may be the reason for King Lunalilo's request to be buried in Kawaiahao Churchyard. The remains of many of the Hawaiian royalty had been buried at the old mausoleum on what is now the Iolani Palace grounds, but in 1865 when the new Royal Mausoleum in Nuuanu Valley was completed, most of them were removed to the new tomb. One of the exceptions was the High Chiefess Kekauluohi, mother of Lunalilo. Indignant about this act of disrespect by King Kamehameha V, Lunalilo vowed that he would not be buried at the Royal Mausoleum, but near his mother. There is some question whether Kekauluohi's bones remained in the old burial place. According to some accounts, they were removed by Lunalilo's family and buried at sea many miles off Diamond Head.

After Lunalilo became King in January 1873, he carried through his decision. On January 31, 1874, just four days before his death, the King approved a final codicil to his will, providing that a suitable tomb for his remains and for

CONTINUATION SHEET ITEM NUMBER 8 PAGE 7

those of his father, Charles Kanaina, be erected in Kawaiahao Churchyard. Upon his death, Lunalilo's casket was temporarily placed in the Royal Mausoleum at Nuuanu until his own tomb could be constructed.

At the request of the executor of Lunalilo's will, on September 19, 1874, the executive committee of Kawaiahao Church dedicated and set apart a site for the erection of the tomb on the west side of the Churchyard. Construction apparently began at the end of the year and was fully underway by January 1875. Robert Lishman, an Englishman who had come to Hawaii from Australia in 1871, was architect and supervisor of the construction. By October 1875, the building was completed.

The tomb was one of the first buildings in Hawaii to be constructed of concrete block, the first being the Kamehameha V Post Office, 1870. It was built in the form of a Greek cross, approximately 11 feet square at the crossing. The roof was of slate and each of the four gables was topped by a small cross. On three sides were narrow stained glass windows. A small porch adjoined the entrance of the tomb. The floor was of smooth concrete and the interior walls of white stucco. The doors and all interior trim were made of stained oak. Over $6,000 was spent for construction of the tomb.

A smooth cemented carriageway leading from the entrance gates to the tomb circled around an open plot on which "rich exotics" were to be planted. Evergreens and other rare trees were also to be added to the grounds. Early pictures show that the eight concrete pedestals which stand around the sides of the tomb were used to hold kahilis (royal standards). The suggestion was made that Lunalilo's father install chimes in the Kawaiahao bell tower in memory of the late King, which on the anniversary of his death could plat "from sunrise to sunset solemn requiems." The suggestion, however, was not carried through.

The night of Tuesday, November 23, 1875, was chosen to transfer Lunalilo's casket to the new tomb. It was customary when necessary to transfer the remains of Hawaiian royalty from one tomb to another, to move them only at night, usually shortly after midnight. This procedure had been followed in 1865 when the new Royal Mausoleum was completed and it was also done at this time. It is said that Lunalilo's father, Charles Kanaiana, requested that a royal salute be fired from the government battery on the crest of Punchbowl while the transfer of Lunalilo's remains from the Mausoleum to the new tomb was being made. On the grounds that Lunalilo was no long King and thus not entitled to a salute, King Kalakaua refused. However, as the hearse carrying Lunalilo's casket moved into Kawaiahao Churchyard on November 23, a loud clap of thunder was heard. Some participants claimed, in fact, to have heard twenty-one distinct claps of thunder as the hearse made its way through the city to the new tomb. It was said by the Hawaiian people that this was a heavenly royal salute to their beloved King Lunalilo.

Kawaiahao Church and Mission Houses
CONTINUATION SHEET ITEM NUMBER 8 PAGE 8

Lunalilo's casket, which was placed in the tomb, was made by William Fischer of native Hawaiian Koa and Kou wood. On it were three silver ornaments made by Mr. Eckart, a crown three to four inches in diameter, a ten by twelve inch plate inscribed in Hawaiian with Lunalilo's name, the dates of his life, and the length of his reign. This plate was surrounded by a wreath of maile leaves, also made of silver. Below this was a silver scroll with the inscription, Ua mau ke ea o ka aina i ka pono (The life of the land is perpetuated in righteousness.), the motto of the Kingdom first uttered by King Kamehameha III in 1843. The casket was covered with a black velvet pall on which six gilt Hawaiian coat-of-arms had been embroidered. This was replaced in 1879 by a similar pall imported from Europe and reported to have cost nearly $1,000.

Less than two years later, Lunalilo's father, Charles Kanaina, died, and his casket, also made of Koa and Kou wood, was placed in the tomb on March 29, 1877.

In 1879 a case was argued before the Supreme Court of the Kingdom of Hawaii to determine the right of possession, care, and control of the tomb. The Legislature had appropriated $400 annually as wages for a keeper of the tomb. This implied the right of the Minister of the Interior, as dispensor of the fund, to claim possession of the tomb. The Minister had, in fact, refused to surrender the keys to the trustees of the estate. The trustees held, however, that it was "quite plain" from Lunalilo's will that he wished his remains to be free of state control and the Legislature had incurred no obligation to pay for the tomb. The case was decided in favor of the trustees.

In 1888 it was found that care of the tomb had been much neglected, and an annual salary $250 for a keeper was provided by the estate. In addition, over $300 was spent in repairing the tomb and painting the iron fence which enclosed the lot. Various other small repairs were undertaken in the ensuing years. In October 1917 vandals broke into the tomb, breaking the locks of the wooden doors to the building. The silver ornaments which adorned Lunalilo's casket were stolen, but detectives recovered them in Florida some time later.

On January 31, 1938, the first ceremony to be held at the tomb since Lunalilo's death took place. At the proceedings which marked the anniversary of Lunalilo's birth, the three royal kahilis (standards) which stood by his casket were to be replaced for the first time since 1874. The ceremony began as the bearers of the new royal kahilis, accompanied by a guard of honor and other participants, marched from Honolulu Hale to the tomb. A red kahili was placed at the foot of Lunalilo's casket and a red and yellow kahili on either side. A bundle of ti leaves entwined with strands of crown flowers was placed on the head of the casket, which was draped with a royal blue velvet pall embroidered with the trimming of the original pall. A traditional rain shower fell during the ceremony at the tomb.

In 1947 alterations and repairs amounting to over $8,000 were undertaken at the tomb. Although unable to determine the exact nature of these alterations, it is pro-able that at this time the slate roof was replaced with asbestos shingles. Two years later in 1949, marble vaults to enclose the caskets were constructed at a cost of $2700.

The tomb, which is usually closed to the public, is opened once each year on the anniversary of King Lunalilo's birthday.

VERBAL BOUNDARY DESCRIPTION

Refer to Tax Map, Island of Oahu, Zone 2, Sec. 1, Plat 32, current in 1978 a copy of which is enclosed with this form. The boundary of the landmark is shown in red on that copy. Beginning at the west corner of parcel 15, proceed in a generally northeast direction along the north side of parcel 15 to the north corner of said parcel; thence general south along the east side of said parcel, continuing in a straight line along the east side of parcel 23 to said parcels extreme east corner; thence in a generally counter clockwise fashion along the entire boundary of parcel 17 returning to the point of origin.

A second unit of the landmark is bounded thus: the boundary of the unit is the boundary of parcel 2 which includes the older parcel 3.

Justification: The boundary includes two units because the two elements of the landmark--the church and the mission houses--have traditionally been understood as distinct elements. Furthermore, there is no practical or historical reason to depart from the physical and distinct fence lines that enclose two distinct physical elements. Each boundary mutually encloses its component elements and setting: (1) Church--church proper, Lunalilo's tomb, cemetery and old schoolhouse; (2) Mission houses--Chamberlain house, first printing building anf first frame house.

DESCRIBE THE PRESENT AND ORIGINAL (IF KNOWN) PHYSICAL APPEARANCE

A 184-foot, ten storied,concrete tower. Best described as a "modernistic" interpretation of a Gothic tower with its accentuated vertical lines terminating at each corner in square pylons with vertical slot, arched windows, arched lintels, and convex curved pointed hip roofs of stucco finish. Projecting above the corner roofs is a higher roof of similar form terminating with a pedestal form of "widows walk" with wrought iron hand rail. At each side of the central roof is a stuccoed dormer similar in form to the corner pylon windows with small gable roofs. The highest point is a mast with a cross arm at the top and various cables which are used to hang signals to transmit information to ships in or near the harbor. At the tenth floor level a projecting observation balcony with the legend "ALOHA" in large block letters is incised in the parapet wall5. The exterior surface is painted white.

The Aloha Tower remains as an important architectural element in the Honolulu skyline and represents the warm welcome and atmosphere the people of Hawaii have always maintained for visitors from across the sea.

Offices are located on all floors. The tenth floor has a projecting observation balcony and the room is mainly open with a central kiosk containing tourist information. There is also a small office in which the harbor pilot works. A radiotelephone is enclosed in this office. Offices are reached by both stair and elevator with three windows on each side connected by a vertical band. The flooring throughout is lineoleum tile.

STATEMENT OF SIGNIFICANCE

The Aloha Tower was at one time the tallest and most prominent building in Honolulu. It is a symbol of Hawaii's investment in tourism and a reminder of the time when sea travel was the main link with the rest of the world. It was a center for the planning of military convoy operations during World War II.

In 1925, the uncompleted Aloha Tower was the center of a fierce little controversy involving the public, the Board of Harbor Commissioners, and the Territorial Legislature. Some wanted no tower at all, some wanted a ten-story structure, while others favored a compromise seven-story building. After several months of debate, the issue was settled in the legislature in favor of the ten-story advocates.

When the tower was finally completed and turned over to the Board of Harbor Commissioners in June, 1926, it was the pride of the islands. It was by far the most imposing building in the territory and offered a spectacular view of Honolulu and its harbor. Then as now, it housed various offices, including the Harbor Master's. The tenth floor was an observatory and also housed a lookout station for the harbor pilots. Vessels calling at Honolulu could see the tower's brillaint white profile from as far as fifteen miles out. For thousands of tourists arriving by ship, it was a symbol of welcome, while for local citizens, an indicator of their ties with the sea and of the importance of sea transportation to Hawaii's economy. Before the advent of trans-Pacific aircraft, it was the landmark in Honolulu's waterfront area.

CONTINUATION SHEET 1 ITEM NUMBER 8 PAGE 1

Immediately after the Japanese attack on Pearl Harbor on December 7, 1941, the United States Navy took over control of Aloha Tower. Access to all but authorized persons was denied, and the landmark was patrolled constantly by armed sentries. This control did not relax even after the war eneded,and the continuing military occupation of the tower became the object of complaint from local citizens. Before a full-scale controversy developed, the United States Coast Guard, who utilized the tower under the authority of the U. S. Navy, relinquished its control on December 20, 1947.

The reason for the wartime secrecy was that the tower had been a control facility for military convoy shipping for the Pacific Theater of Operations. Many of the convoys that supported the various island invasions were formed in Honolulu under the control of the Aloha Tower offices.
In 1947, the green camouflage paint was sandblasted from the tower and the brillian white paint replaced. Once again, Aloha Tower welcomed visitors arriving aboard cruise ships also recently released from military control. However, it was not long before the emphais in travel shifted from passenger vessels to aircraft. Before long, a passenger ship in Honolulu Harbor became an unusual sight.
Aloha Tower still stands to welcome visitors, however, and the Harbor pilots still carry out their watch over the activities below. Recently, the tower became the main terminal for a new inter-island hydrofoil commuter vessel system.

National Register of Historic Places Registration Form

This form is for use in nominating or requesting determinations for individual properties and districts. See instructions in *How to Complete the National Register of Historic Places Registration Form* (National Register Bulletin 16A). Complete each item by marking "x" in the appropriate box or by entering the information requested. If an item does not apply to the property being documented, enter "N/A" for "not applicable." For functions, architectural classification, materials, and areas of significance, enter only categories and subcategories from the instructions. Place additional entries and narrative items on continuation sheets (NPS Form 10-900a). Use a typewriter, word processor, or computer, to complete all items.

1. Name of Property

historic name SMYTH, MABEL, MEMORIAL BUILDING

8. Statement of Significance

Applicable National Register Criteria (Mark "x" in one or more boxes for the criteria qualifying the property for National Register listing.)
☒ A Property is associated with events that have made a significant contribution to the broad patterns of our history.
☐ B Property is associated with the lives of persons significant in our past.
☒ C Property embodies the distinctive characteristics of a type, period, or method of construction or represents the work of a master, or possesses high artistic values, or represents a significant and distinguishable entity whose components lack individual distinction.
☐ D Property has yielded, or is likely to yield, information important in prehistory or history.

Criteria Considerations (Mark "x" in all the boxes that apply.)
Property is:
☐ A owned by a religious institution or used for religious purposes.
☐ B removed from its original location.
☐ C a birthplace or grave.
☐ D a cemetery.
☐ E a reconstructed building, object, or structure.
☐ F a commemorative property.
☐ G less than 50 years of age or achieved significance within the past 50 years.

SMYTH, MABEL, MEMORIAL BUILDING
Honolulu, Hawaii

Narrative Description

The Mabel Smyth Memorial Building was funded through popular subscription and was built and maintained as an expression of the Territorial and then the State of Hawaii's respect for the nurses and doctors of the developing medical profession. Dickey's 1937 design for the Memorial Building is a two-storied, L-shaped concrete structure, capped by a tiled hip roof with overhanging eaves. The building measures approximately 42 x 69 feet, and is positioned on the parcel so that it could take advantage of the widest span, almost abutting the property line in back. The main entrance to the building is from the parking lot via two sets of stairs which lead to a central landing before the door. Forming a railing is a design of `ape leaves set between low posts. The `ape motif is repeated above the door in a large panel. Among the leaves is a snake from the medical profession's symbol, the caduceus. While the building is not symmetrical, it presents a balanced facade. To the left of the entrance are the offices and larger rooms. Moving from the entrance are four bays of offices each with a single large metal casement window pair per floor. The windows are organized within a vertical panel with ape leaf reliefs below the second story windows. At the far left end of the building are the larger Alice Yates Memorial Room on the ground floor and the former Charles Adams Medical Library above. These rooms have larger banks of windows, three sets of casements per floor. Once again, the ape motif is repeated below the second story windows. To the right of the entrance is the auditorium space. It is revealed on the exterior by inset vertical panels corresponding in dimension to the window bays on the left hand side.

When complete, it contained an air-conditioned auditorium that seated 346 people; various meeting halls that were designated to honor other outstanding nurses (i.e. the Alice Yates Lounge and Lanai, the Stella Matthew Room); provisions for the Dr. Charles R. Adams Medical Library; classrooms and staff offices; kitchen, dressing room and toilet facilities; and for its time, a quite innovative parking space that was commodious and accessible from the two major streets it bordered. The layout of the interior has not changed significantly. However, in 1964 the Charles R. Adams Medical Library was moved to a new, larger structure adjacent to the Smyth Memorial Building, and this affected how the latter functioned from then on.

11/93

United States Department of the Interior
National Park Service

National Register of Historic Places
Continuation Sheet

Section number 7 Page 2

The walls of the entry and lobby still are covered with the original block paneling of mahogany and primavera wood veneers, slightly water damaged and peeling through recent neglect, but easily restored. The auditorium has suffered from asbestos removal procedures, normal wear and tear, and the introduction of hi-tech multiple screen video equipment, yet it remains in continuous use. It retains many of its better features, such as the sequenced subtly shaded concrete wall panels, the hanging light fixtures, etc. The Alice Yates Lounge on the ground floor no longer has wainscoting carved with the 'ape motif, described in early articles about the building (only two panels on the double door leading to the lanai are preserved); but the door serving the former medical library, on the second floor, is ornately carved with torch ginger, and remains a beautiful example of 'Hawaiian Style' detailing. Overall, the high ceilings, ample proportions and airy lightness in the main reception room and now vacant offices, attest to the hospitable spirit and gracious life style that Dickey expressed in his architectural concepts.

The original blueprints for the Smyth Memorial Building, along with most of Dickey's professional archives, were, according to Dickey's biographer, Robert Jay, discarded or dispersed by the successors' firm when it moved offices a few years after his death. Only one modification of kitchen facilities and the regendering of toilets, submitted by Dickey on December 5, 1939, before the completion of the building, was deposited in the hospital archives and thus is extant. The measured drawings of the existing building were produced by Architects Hawaii, Ltd., Honolulu, in May 1978. An overall ground plan of Queen's Hospital, done by Dickey Associates in November 28, 1944 (also found in the hospital archives, indicates that the silhouette of the building and its property boundaries had not changed between 1944 and 1978. In 1981, a storage space for an annual Christmas fund raising projects run by hospital volunteers, was added to the rear of the building by S & M Sakamoto, Inc. In 1991, ownership of the building and property passed from the Queen's Medical Center to the State of Hawaii, in an exchange for nearby undeveloped land that was needed for expansion of medical facilities. The building now houses the State Capitol Tour and Information Program, a division of the Governor's Office of Information; it is designated in long term plans for multiple uses.

Section number 8 Page 1

Narrative Statement of Significance:

The Mabel Smyth Memorial Building is significant as an example of the work of architect C.W. Dickey and for its associations with the medical profession in Hawaii. In 1937, in reaction to the sudden and early death of Mabel Leilani Smyth, who had for eight years been Superintendent of the Public Nursing Service, there was a Territorial-wide drive to commemorate her accomplishments. A unique center was envisioned, one that would be headquarters for the entire medical profession, in which nurses' and doctors' associations could convene their meetings; a research library could be housed; and where people could gather for educational programs and social interactions. Eventually, about $100,000. in money and services was raised from the community at large. Queen's Hospital provided a small triangular plot of land (28,213 square feet) at the makai/Ewa (western) end of its property, where Punchbowl and South Beretania Streets intersect. Plans were submitted by the locally noted architect, C.W. Dickey, who had also designed the hospital's Harkness Nurses' Residence built in 1932.

The Directory that was posted when the Mabel Smyth Memorial Building was opened on January 4, 1941, is a clear indication of how the building was meant to function:

First Floor:
- Offices of the
  - Nurses Association, Territory of Hawaii Nurses Association, City and County of Honolulu Board of Nursing Registration Nursing Service Bureau
  - Physicians' Exchange
- Nurses Board Room
- Alice Yates Room - Nurses' lounge and lanai
- Auditorium - available to the community for lectures, conferences and performances.

Second Floor:
- Charles R. Adams Medical Library - Gift of Mrs. Chas. R. Adams. Furnishings - Gift of Mrs. Walter Dillinghams.
- Physicians Board Room.
- Offices of the
  - Hawaii Territorial Medical Association.
  - Honolulu County Medical Society.

Section number 8 Page 2

The building has fine qualities as a modest, sincere architectural monument. It is sensitively positioned in relation to the buildings and landscaping around it and provides a good human scale. Its decorative facade is uniquely Hawaiian and although representative of the Art Deco period, it has a timeless attractiveness. It thereby is a significant historic physical entity in the Capitol District of Honolulu.

The people associated with the building, the person whose name it honors, and its architect are also are significant in their own right. The life of Mabel Leilani Smyth (1892-1936) was marked by her dedication to the well-being of others, by her innate authority and the affection that her personal qualities drew forth, and by the improvement in public health nursing that she achieved throughout the Hawaiian Islands. She, more than anyone, pioneered in the development and organization of public health nursing in the pre-World War II era.

Born in Kona of a half-Hawaiian mother and an Irish English Captain of the Inter-Island Fleet, Mabel Smyth did not come to Honolulu for schooling until she was fifteen. At age twenty two she met her goal of attending Springfield Hospital Training School for nurses in Manchester, Massachusetts. When she returned home, she became a district nurse at Palama Settlement, and eventually she headed their nursing program. At thirty, she was again on the mainland for training, receiving her degree in Public Health Nursing at Simmons College in Boston. At thirty five, she became Director of Public Health Nursing in the Territorial Board of Health, a position she held for eight years. Always seeking knowledge of developments in her field, Smyth attended many conferences in Washington and throughout the United States, and as a representative of Hawaii was recognized for her unusual capability. Among the innovations for which she is still known was the organizing of the first well-baby clinic in Hawaii and the campaigns she led to raise midwifery standards. Among the honors conferrnd on her during her lifetime were election to the Presidency of the City and County Nurses Association, and the Directorship of the Bureau of Maternity and Infancy. At age forty two, she died of complications from an operation. Increasingly, her status as a Hawaiian woman who embodied so many outstanding qualities and achievements, has relevance for the history of the Hawaiian people in the post-contact period, and for the history of women in Hawaii.

Section number 8 Page 3

Charles William Dickey (1871-1942) was born in California. His mother was a member of an extended Kamaaina family, prominent in business and civic affairs in Hawaii, that descended from the earliest American missionaries. When he was two, his parents moved to Haiku, Maui, where he lived until he was sent back to Oakland, to attend high school After graduation with a degree in architecture from the Massachusetts Institute of Technology in 1894, Dickey came to Hawaii to work. He set up practice with several partners and was successful. In 1904, he decided to move back to the Bay Area; and in 1924, he returned to Honolulu, where he remained professionally active until his death. In Hawaii and in California, Dickey designed schools, banks, theaters, churches, municipal buildings, hotels, extravagant imposing residences, and, due to his own priorities, many small reasonably priced single family bungalows.

C.W. Dickey holds the central position in Hawaii's architectural history, a fact that is becoming increasingly recognized. This is not only because of the sheer number, diversity and quality of the buildings that he designed, particularly during the last phase of his career in Hawaii. It also is because of his direct influence on the many architects that he trained in his offices, who came into prominence during the building boom following World War II, and the continuing influence of his existing works on contemporary younger architects. Primarily, however, it is because Dickey very consciously set out to create an indigenous architectural style. As he assimilated and transcended the succession of popular styles of his period, and the older styles that he encountered during his travels abroad, he was creating his own style that met the unique environmental conditions and the special demographics of Hawaii.

His aesthetic criteria--which readily affirmed and incorporated the traditional scale, forms and motifs and standards of workmanship that are associated with the many different cultural heritages of peoples of the Pacific and Western countries who coexist on the Islands--express the humanitarian ideals shared by the people of Hawaii. Perhaps the most significant and uniquely Hawaiian characteristic of the Mabel Smyth Memorial Building is the use of low relief panels featuring the 'ape leaf motif. In native Hawaiian lore, this taro-like plant was planted by gates or placed under the mats of the sick to ward off evil spirits. Thus, Dickey's exterior design incorporates a familiar local image, and one that evokes a traditional Hawaiian use of floral metaphor, to convey the essential purpose of this commemorative edifice.

DESCRIBE THE PRESENT AND ORIGINAL (If Known) PHYSICAL APPEARANCE

The present United States Post Office, Custom House and Court House in Honolulu was designed by architects York and Sawyer of New York City. The original portion, as well as the later addition, are in the Spanish Colonial Revival style with certain modifications. The original portion was designed in 1918 and was built in 1921-22. It is "U"-shaped structure three floors in height, with the central portion containing the courtrooms in the upper floors (being equivalent to four floors) full basement, and two square towers rising to six floors. The approximate overall dimensions of the building in plan are 177' x 143'. The building fills the mauka (east) half of a square city block. The Ewa (north) side of the original building contains an open-air arcade where postal business is conducted. The arcaded courtyard faces mauka (east) toward Iolani Palace, the former State Capitol. The windows facing the courtyard are arched and covered with decorative window grilles. The capitals in the arcade are modified Corinthian. The two marble stairs, leading to the second floor courtrooms, wing offices, and the lanai overlooking one of the 1930 courts, are symmetrical. The upper passageways are barrel vaulted with groin vaults at the landings. The interior plaster walls are plain.

The addition was designed in 1929 by the Treasury Department using the same style as the original building. It was constructed in 1930 makai (west) of the existing structure. The original portion is set back from King Street with a lawn; the addition was built with a lawn on Mililani Street (Diamond Head side-south), but Queen Street (makai side-west) and Richards Street (Ewa side-north) are built to the sidewalk. The 3-story addition contains two courts, one enclosed with access for vehicular traffic Diamond Head to Mililani Street, and the other open for vehicular traffic Ewa towards Richards Street. The functions of the spaces of the building, in both portions, have not changed appreciably since being designed. Both were constructed using caissons, a steel skeleton frame with concrete beams, and concrete ribbed floor slabs.

The architectural character of the exterior with its thick plaster walls, arched openings, and deep overhanging tile roofs has been retained in spite of minor changes over the years. Local public groups in the past have strongly protested changes which would have altered the building's basic design. It is unfortunate that jalousies have been installed in place of the original windows in the courtrooms, and that many of the decorative window grilles have been cut and original portions of window sash removed to install air conditioners. These elements could be modified to better suit the overall architectural design. The 3-story height keeps the building comfortably in scale with the other significant structures in the Honolulu Capital District.

STATEMENT OF SIGNIFICANCE

After the annexation of the Hawaiian Islands by the United States in 1898, many offices of the federal government, as well as those of the Territory of Hawaii, were housed in the former royal Iolani Palace. The Palace was used as the main governmental executive office building, and this led to eventual overcrowding and the desire on the part of Territorial officials for federal offices to be housed in a separate building. Successive early Territorial governors -- Sanford B. Dole, George R. Carter, Walter F. Frear and Lucius E. Pinkham -- agreed that a separate federal office building should be constructed in Honolulu. Their efforts culminated in the erection of the original portion of the present United States Post Office, Custom House and Court House, completed in 1922.

This building including its 1930 addition is a good example of the Spanish Colonial Revival style and its adaptation to Hawaii. Its design was later echoed by Honolulu Hale (City Hall) by architects Miller, Dickey, Wood, Rothwell, Kangeter and Lester in 1927 and by the YWCA Building by architect Julia Morgan in 1927. This building forms an integral part of the historical style and scale continuity of Honolulu's Civic Center, together with the adjacent Aliiolani Hale (State Judiciary Building, 1872-1874), and Iolani Palace (1879-1882), two of Honolulu's most significant buildings.

DESCRIBE THE PRESENT AND ORIGINAL (If Known) PHYSICAL APPEARANCE

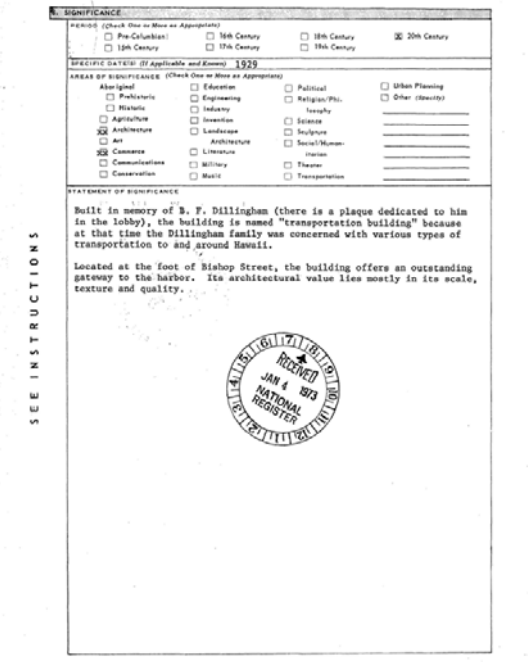
The Dillingham Transportation Building is a four story Italian Renaissance concrete and concrete block structure with three connected wings. The first floor features an arcade that extends between the projecting wings. The cut stone arches span between massive rectilinear columns which support a classical, dentilled cornice creating a horizontal band surrounding the building. The columns extend above the cornice creating piers between a wrought iron hand rail and support classical concrete urns. The arcade roof is a simulated porch at the second floor level.

The main entry arch is flanked by rectilinear openings decorated with a twisted rope pattern. Above each of the openings is a medallion depicting a square rigged sailing ship and a modern (at the time of construction) steamship. The main entry at each of the other two projecting wings is a rectilinear opening with massive scrolls in terra cotta above.

The upper three floors are simple planes pierced by rectilinear window openings, the only break in the stucco finish being at the rusticated stone quoins. At the upper portion of the wall, below the eave, a frescoed frieze is punctured with circular attic vents with a wheel spoke design.

A Spanish tile roof in a hip form is supported at the eave overhang by exposed rafters. Between rafters the eave is painted with bright designs.

The entry lobby is a wonder of design and decoration. Multi-toned glazed brick in many patterns and textures create a unique floor covering with the center being concentric circles ending in a multi-pointed star. Walls are buff marble divided with stripes of gold mosaic tile strips and red marble. The ceiling consists of paneled beams with gold, black, green and red designs both on the beams and on the ceiling between, surrounded at the perimeter by a crown molding. Elevator doors are of "modernistic" designs cast in aluminum.



After this elaborate entry all other interior spaces are of simple business-like design. The first floor actually consists of the ground floor and a mezzanine floor.

Landscaping is minimal but tasteful in a small setback space between the building and sidewalks. Along the street a row of coconut palm trees overlook Bishop Street.

Currently, the building is in good repair and receiving adequate maintenance.

STATEMENT OF SIGNIFICANCE

Built in memory of B. F. Dillingham (there is a plaque dedicated to him in the lobby), the building is named "transportation building" because at that time the Dillingham family was concerned with various types of transportation to and around Hawaii.

Located at the foot of Bishop Street, the building offers an outstanding gateway to the harbor. Its architectural value lies mostly in its scale, texture and quality.

NATIONAL REGISTER OF HISTORIC PLACES
INVENTORY -- NOMINATION FORM

CONTINUATION SHEET ITEM NUMBER 8 PAGE 1

The Dillingham Transportation Building is architecturally significant as a good example of the Mediterranean revival style applied to a commercial structure. The first story round arched arcade, upper story quoins and the low pitched, tile, hipped roof, well convey the style. The Mediterranean and Spanish mission revival styles enjoyed tremendous popularity in Hawaii during the twenties. These styles, the closest European equivalents to tropical design, were considered to be the most appropriate forms for Hawaii's climate with their arcades providing a sense of airy openness. The Dillingham Transportation Building is one of a number of downtown buildings to employ these styles, and is the most imposing of the Mediterranean revival buildings in the area.

The Dillingham Transportation Building is an integral part of the historic architectural patina of the now highrise-pocked Bishop Street area. Commanding the entire block on Bishop between Queen Street and Nimitz Highway, this building with its moderately formal facade mediates between the more highly embellished Second Renaissance Revival and less ornate Spanish mission revival styles. Free from the more formal restraints of the Beaux-Arts tradition, yet employing Renaissance revival elements in a commanding way, the Dillingham Transportation Building stands as a significant architectural landmark in Honolulu's downtown area. The building harmonizes well with its eclectic neighbors, the Alexander & Baldwin Building, with its excellent adaptation of Oriental and European features, and the Italian Renaissance inspired Alexander Young Hotel, First National Bank and Davies block (which is no longer extant).

The building is also significant for its associations with Benjamin Franklin Dillingham, the founder of Dillingham Corporation, whom the building memorializes. In 1889, after devoting twenty years to the hardware business, B. F. Dillingham created the Oahu Railroad and Land Company. This company was primarily responsible for the development of the 160 mile Oahu Railroad (NR). Through these rail interests, the corporation became involved with the development of the various sugarcane plantations along its route, and later expanded its cane activities to the islands of Kauai, Maui and Hawaii with the McBryde, Kihei, Puna and Olaa Sugar Companies. In 1910, the company received the government contract to dredge Pearl Harbor, which provided the company with a solid financial base. It has greatly expanded upon this base and presently ranks among the major three corporations in the state.

DESCRIBE THE PRESENT AND ORIGINAL (If Known) PHYSICAL APPEARANCE

The U. S. Immigration complex consists of five buildings: administration building (most visible and important), detention building (to the right and rear of the administration building, used to detain those immigrants waiting for proper clearance to enter Hawaii), lounging shed (an open pavilion directly to the rear of administration building), garage and waiting shed (to the right of the administration building) and the gardener's cottage (no longer standing).

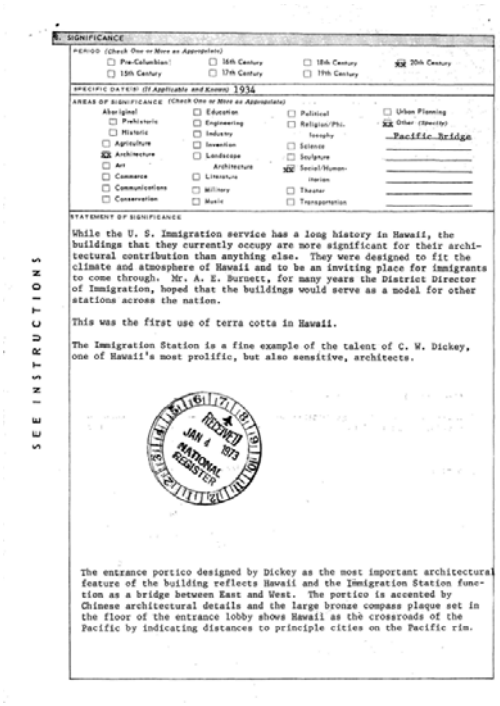
The four remaining buildings represent a complex of buildings each reflecting its own particular function but totally related to the other buildings by scale, texture and form. The dominating feature of all of the structures is the high double-pitched tile hip roofs on all of the buildings, commonly referred to as the "Dickey" roof.

Although Herbert C. Clayton was the architect who contracted to design the building, it is quite evident that the architect associated with him for this project had the major design role, the sensitive talent of C. W. Dickey is everywhere in evidence. An interview with Mr. Dickey, July 27, 1934 in the Honolulu Star-Bulletin best describes the intent and execution of the complex in the designer's own words:

"In designing the new immigration station buildings the main objective was a group of buildings expressing the spirit and environment of Hawaii and at the same time maintaining well balanced and well proportioned masses, graceful lines and a pleasing color effect."

"This meant a wide departure from the more or less stereotyped stations of the mainland and it required no small amount of persuasion and diplomacy to get such a design accepted...."

"In general the buildings consist of low lying masses of cream colored stucco walls surmounted by graceful sloping roofs of variegated green and russet tiles."



"The administration building facing the Ala Moana has a long shallow court on its main front, with a lofty entrance portico treated with a touch of Chinese architecture in its detail, which is accented and enriched with polychrome terra cotta. This portico is the most important architectural feature of the group and is entirely of terra cotta with a polychrome ceiling in accoustical terra cotta, a floor of varied shades of dark red and brown and Roman Travertine and a striking aluminum grill across the inner wall. In the center of the floor is a large bronze many pointed star showing the directions to all the principal ports of the Pacific."

The receiving building, facing the harbor, is a 2 story structure "of simple design with porches and overhanging eaves producing the deep shadows so necessary to produce coolness and comfort in Hawaiian architecture. It is seen through an ornamented aluminum fence of very effective modernistic design."

"The careful study of line, proportion and color was not confined to these two important buildings, but was extended to the lounging shed, and shed, gardener's cottage, all of which are well worth one's attention."

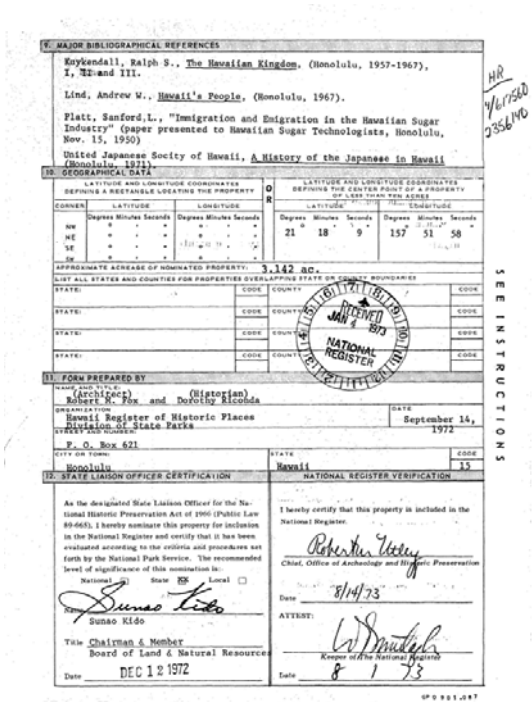
STATEMENT OF SIGNIFICANCE

While the U. S. Immigration service has a long history in Hawaii, the buildings that they currently occupy are more significant for their architectural contribution than anything else. They were designed to fit the climate and atmosphere of Hawaii and to be an inviting place for immigrants to come through. Mr. A. E. Burnett, for many years the District Director of Immigration, hoped that the buildings would serve as a model for other stations across the nation.



This was the first use of terra cotta in Hawaii.

The Immigration Station is a fine example of the talent of C. W. Dickey, one of Hawaii's most prolific, but also sensitive, architects.

RECEIVED JAN 4 1973 NATIONAL REGISTER

The entrance portico designed by Dickey as the most important architectural feature of the building reflects Hawaii and the Immigration Station function as a bridge between East and West. The portico is accented by Chinese architectural details and the large bronze compass plaque set in the floor of the entrance lobby shows Hawaii as the crossroads of the Pacific by indicating distances to principle cities on the Pacific rim.

"Taken all in all, these buildings have an inviting air of comfort and hospitality and at the same time fulfill all the necessary functions of an immigration station in Hawaii."

Removed from Ala Moana Boulevard by a broad sweeping lawn and spreading shade trees, the serene repose of the complex is emphasized. The inner courts between buildings are landscaped with the same delicate care and create a feeling of cool, quiet private gardens.

Currently, the buildings are receiving very good maintenance and are in excellent repair.

Falls of Clyde: National Historic Landmark Study

(Delgado 1988)

Obtained September 2013 from:
National Park Service Website,
Meritime Heritage Program,
Maritime Landmarks, Large Vessels
http://www.nps.gov/history/maritime/nhl/falls.htm

Falls of Clyde
National Historic Landmark Study
by James Delgado, 1988
Designated April 11, 1989

Present and Historic Physical Appearance

The 1878 four-masted ship *Falls of Clyde* is a floating exhibit moored in Honolulu harbor. Located at the Hawaii Maritime Center off Pier 7, *Falls of Clyde* was rescued from destruction, moved to Honolulu and first restored and opened to the public in 1968. Since then, the vessel has undergone continual restoration. *Falls of Clyde* is listed in the National Register of Historic Places at a National level of significance.

Falls of Clyde *as restored and on display at Pier 7 in Honolulu in 1986. Photo courtesy Hawaii Maritime Center.*

FALLS OF CLYDE AS BUILT AND MODIFIED

As built in 1878, *Falls of Clyde* is an iron-hulled, four-masted vessel originally rigged as a ship, later downrigged to a bark, subsequently dismasted, and then restored in 1970 to her original ship rig. *Falls of Clyde* is 266.1 feet in length, with a 40.0- foot beam and a 23.5-foot depth of hold. *Falls of Clyde* is registered at 1,807 gross and 1,741 net tons.[1] Built staunchly with iron Z-bar frames and double riveted iron plate laid as inner and outer strakes, *Falls of Clyde* was rated 100A1 by Lloyd's of London, the highest rating the conservative maritime insurance firm could provide. *Falls of Clyde* was built to the British medium clipper model. Slower sailers than the sleek tea clippers of the 1860s and 70s, the fuller-bodied medium clippers made fair passages with greater capacity than the earlier clippers.[2] Full-rigged on her fore-, main-, mizzen-, and jiggermasts, *Falls of Clyde* was rigged with royals over single topgallants. In 1899 the vessel was downrigged to a bark; the squaresail yards on the jiggermast were replaced with a spanker boom and gaff which increased the vessel's maneuverability, an asset when sailing along a coastline. Typical for the period and type of construction, *Falls of Clyde* was rigged with wire rope.

The vessel, built for the general carrying trade, had a large open wood deck interrupted only by three hatches, and two riveted iron deckhouses which housed the galley, cook and steward's cabins, and the young "brassbounder" apprentices. *Falls of Clyde* has a 34-foot forecastle deck and a 23-foot poop deck. The forecastle sheltered the crew and the ship's large patent windlass. The poop housed a large dining saloon with birdseye maple and mahogany panels and pilasters, polished brass hardware, and marble sideboard. Cabins for officers and passengers line the saloon; aft are the master's stateroom and a

stairway leading above into a shelter house on the poopdeck. Also on the poop deck is the ship's wheel and wheel box, binnacle, and an ornate skylight for the dining saloon. Similar to other British deepwatermen of the period, *Falls of Clyde* is a well-built vessel with a workable combination of speed, cargo capacity, and ease and economy of operation.

Between 1898 and 1901 *Falls of Clyde* underwent modification after her sale to American owners and entry into service as a Hawaiian transpacific passenger and freight-carrying vessel. These modifications, in addition to re-rigging *Falls of Clyde* as a bark, included removing the crew quarters from the forecastle and building a wooden deckhouse forward with galley, accommodations for 12 men, and a cabin for the cook and steward. The forecastle was then converted into an icehouse for fresh provisions. With the relocation of the galley, a steam-powered donkey engine was installed in the iron deckhouse that had originally housed the galley. A small wooden shelterhouse was added to the poopdeck for passenger comfort.[3]

In 1907 *Falls of Clyde* was once again modified when she was converted into a sailing oil tanker. Ten riveted steel bulk liquid cargo tanks, five on the port, five on the starboard side, were built into the ship. The tanks, reinforced by cross braces, are separated into two levels, with smaller wing or "summer" tanks atop larger tanks. The steel tops of the wing tanks form part of the weather deck; two 10-foot wide steel deck sections run from the poop to the forecastle on the port and starboard sides of the vessel, with the original wooden deck running in a 20-foot wide section along the centerline. Each tank is marked by a 3- x 4- x 2.6-foot steel expansion trunk on the steel sections of the weather deck. Steel ladders running through the trunks provide access to the tank interiors and control valves. A large pumproom and boilerroom were added forward behind an oil- tight steel bulkhead. The boilerroom, a 20- x 30-foot space, has a single oil-fired "Scotch" fire-tube boiler, a D.C. dynamo, and a fuel-feed pump. A short smokestack originally rose above the weather deck from the boiler room; the opening remains in the deck, but the stack has been removed. The pumproom, divided into two levels, contains large feedwater tanks for the boiler on its upper ('tween deck) level. The lower pumproom, in the hold, is reached by a single steel ladder. It contains a 10-inch horizontal reciprocating oil cargo pump and a similar 8-inch saltwater ballast pump, both manufactured by the George P. Dow Pumping Engine Co. of San Francisco. Steel piping, including pipes for heating crude oil and molasses cargoes, transfer and discharge pipes, and control valves, line the pumproom.[4]

After 1907 the vessel underwent little change until after 1922, when her yards, royals, and topmasts were sent down and *Falls of Clyde* was converted to a fuel-oil barge and floating gasoline depot. The lower masts were later cut down to just above the weather deck and the bowsprit was removed. In 1970 *Falls of Clyde*'s rig was restored. During restoration the masts were replaced with rolled and plug-welded steel joined to the original iron lowermast sections. New steel lower and topsail yards produced by the Scott-Lithgow Shipyard in Glasgow, Scotland, the vessel's builder, and new wooden topgallant and royal yards, jibboom, and spanker boom turned in Oregon to original specifications, were installed and the vessel was re-rigged with wire rope in a historic fashion. Restoration of the vessel's hull, equipment, and decks has proceeded since 1968; the only major areas left unrestored in 1988 are the boilerroom, pumproom, and weather deck. All restoration work has followed original plans and employs in-kind replacement and adherence to historic technique.[5]

Statement of Significance

Falls of Clyde *as built in 1878 as a four-masted full-rigged ship. Illustration courtesy of Hawaii Maritime Center, Inc.*

The 1878 ship *Falls of Clyde* is the world's only surviving four-masted full-rigged ship. Built in Great Britain in the last quarter of the 19th century during a shipbuilding boom inspired in part by increased trade with the United States, *Falls of Clyde* made several voyages to American ports, notably San Francisco and Portland, Oregon, while under the British flag. Sold to American owners in 1898, *Falls of Clyde* gained American registry by a special act of Congress in 1900. Henceforth she was involved in the nationally important Hawaiian transpacific sugar trade for Capt. William Matson's Matson Navigation Co., a shipping firm of international scope and significance that continues in business. *Falls of Clyde*, ninth vessel acquired by Matson, is the oldest surviving member of the Matson fleet. After 1907, *Falls of Clyde* entered another nationally significant maritime trade, transporting petroleum as a sailing oil tanker. Specifically modified for the petroleum trade as a bulk cargo carrier, *Falls of Clyde* retains integrity of design, materials, and workmanship, and is of exceptional national significance as the oldest surviving American tanker and as the only surviving sailing oil tanker left afloat not only in the United States but also in the world.

The preceding statement of significance is based on the more detailed discussion that follows.

CONSTRUCTION AND EARLY CAREER OF *FALLS OF CLYDE*

The Clyde River shipbuilding firm of Russell and Co., a scarcely five-year-old concern in 1878, built more than 500 iron and steel-hulled squareriggers at their Glasgow, Scotland yard. By 1883, the firm was noted as having "already acquired an excellent reputation, more especially for the large and splendid sailing ships which they have turned out from year to year." [1] In 1878 Russell and Co. laid down and launched the first of nine four- masted vessels they would build for the Glasgow Falls Line of Wright and Breakenridge. The fleet, named for Scottish waterfalls, commenced with *Falls of Clyde.* Built for trade between Britain and India, the ship also journeyed into the Pacific, stopping at Melbourne, Australia; Auckland, New Zealand; Bangkok; Hong Kong; Shanghai; Portland, Oregon; and San Francisco. Launched in response to a shipping boom in Great Britain, *Falls of Clyde* was specifically designed to

carry bulk cargoes quickly and cheaply. In 1886, on the occasion of the ship's arrival in New Zealand, the editors of the *Auckland Star* stated:

Four-masted vessels are rapidly coming into favour, they being found to be equally as handy and as cheap in their working as the old three- masters, whilst at the same time larger hulls, and consequently greater carrying power, are also obtained, two most important matters in these days of cheap rates. As a proof of the carrying power of these vessels, it may be mentioned that the Falls of Clyde *has on board some 3500 tons of general cargo, of which some 3000 tons are for this port....*[2]

Carrying cargoes such as cement, jute, iron, grain, and general merchandise, *Falls of Clyde* principally plied her trade as an "Indiaman." Her maiden voyage, commencing at Greenock, Scotland, on April 20, 1879, brought *Falls of Clyde* to Karachi and thence back to London on December 18 of the same year. Over the next few years, the ship also sailed to Rangoon, Calcutta, and Bombay.

While continuing to trade as an Indiaman, *Falls of Clyde* made 10 voyages to American ports while under the British flag. Sailing to San Francisco, and Portland, Oregon, for wheat, *Falls of Clyde* also made one voyage to New York. The voyages to San Francisco were particularly important, for they involved the ship in one of the United States and Britain's most significant maritime trades, the California grain trade. By the mid-1850s many gold-seeking migrants to California had turned from the placers to another profitable aspect of the Golden State--agriculture and ranching. The great Central Valley was planted with wheat, which flourished in the hot, dry climate the valley offered. Gradually wheat crops increased, and by 1854 there was a sufficient surplus to allow for the first export, by ship, of wheat abroad. The wheat business boomed, beginning in 1858 when one astute San Francisco merchant, Isaac Friedlander, commenced buying up crops and exporting them to grain-hungry Europe and Britain in a fleet of ships he chartered for the purpose. In 1860, the wheat harvest was 5,928,470 bushels, "nearly five times the production of the rest of the United States west of the Rockies."[3] The amount exported each year increased, and by 1875 the entire Central Valley had become "a vast wheat growing empire, with great ranches, 20,000 acres in extent, planted to the crop year after year."[4] Historian Gerald Nash commented

Wheat proved to be as great a boon to California's economy as gold had been in an earlier era. California produced a hard, dry, and unusually white wheat that became particularly popular on the Liverpool Corn Exchange. Environment, entrepreneurship, and technology combined to support the claim of the editor of the California Farmer *in 1869 that "California is now esteemed the granary of the world"....the initiative for California's entry into world wheat markets was taken by a restless group of San Francisco merchants in 1860, spurred by what they considered to be the state's isolation from lucrative eastern and international marketing outlets. After more than a decade of strenuous efforts, by 1875 they succeeded in capturing a large share of the British wheat trade.*[5]

To carry California's wheat to market, businessmen devised a system of waterborne and rail transport. From the valley, wheat was taken by wagon or rail to the Sacramento and San Joaquin Rivers, and thence down to the bay and the grain port of Port Costa on Carquinez Strait, or into San Francisco. There, large numbers of vessels, known colloquially as the "wheat fleet," called to discharge their bulk cargoes and load sacks of wheat grain.

The United States' merchant fleet boomed in response to the trade, with large "downeasters" built at east coast yards sailing round Cape Horn for California. Yet the largest number of vessels came from 14,000 nautical miles away. From Great Britain, a large number of iron, and later steel-hulled large capacity ships, also built for speed and economy of handling, were launched and sent to California since the trade demanded vessels that made good time, carried as much cargo as possible, and required small crews. The British medium clippers, or deepwatermen, of the 1870s and 1880s answered admirably to the purpose. In 1881-1882, for example, a record harvest in California resulted in a fleet of 559 vessels carrying more than 1,000,000 tons of wheat sailed out the Golden Gate; only 154 were American-flag ships.[6] *Falls of Clyde* made voyages to San Francisco in 1886, 1888, 1892, 1895, and 1898. She also sailed up the Columbia River for Willamette Valley wheat, calling at Astoria and Portland, Oregon, in 1893

and twice in 1897. On November 30, 1897, for example, the Portland *Oregonian* reported that "two more good sized wheat cargoes cleared at the custom- house yesterday, and will go down the river this morning. The vessels were the British bark *Principality*, with 95,768 bushels...and the British ship *Falls of Clyde*, with 100,290 bushels of wheat valued at $82,739....Both of the vessels are for Queenstown or Falmouth for orders."[7]

Falls of Clyde made her last voyage under the British flag from London to San Francisco in 1898, arriving at the latter port on November 15. Within a month the vessel was sold through intermediaries to Capt. William Matson of San Francisco. On December 21, 1898, the San Francisco *Call* reported that "the master and crew left the vessel yesterday and her new owners will proceed to get her ready for the Hawaiian trade. The yards are to be taken off her jiggermast and she will be turned into a four-masted bark." Matson, a Swedish emigrant to the United States in 1864, arrived in California in 1867 as a merchant seaman. In 1882 Matson and partners acquired the schooner *Emma Claudina*, Matson's first sea command and progenitor of a fleet of sailers, steamers, liners, and freighters. The signing of a reciprocal trade treaty between the United States and the Kingdom of Hawaii in 1876 opened the Hawaiian islands to large-scale trade and paved the way for the introduction of Hawaiian cane sugar to the United States. Among the shipping lines created by the booming sugar trade was Matson's. Matson, teaming with California and Hawaii sugar magnate Claus Spreckels, particularly profited.

As his business boomed, Matson acquired additional larger ships; the ninth vessel to be added to the fleet was *Falls of Clyde*.[8] The vessel gained American registry through shrewd manipulation on Matson's part. According to U.S. law, *Falls of Clyde* needed American registry to trade between American ports, a right denied to foreign-built and registered vessels. This problem surfaced for American owners of foreign bottoms with the annexation of Hawaii as an American territory in July 1898. Only a major rebuilding at a port in the U.S. would bring American registry, so Matson, like other shipowners, sought and obtained temporary Hawaiian registry in the hope that Hawaiian vessels would be "grandfathered" into American-register ships. When this strategy failed, lobbying added language to the 1900 organic act establishing the territory of Hawaii that specifically granted U.S. registry to certain vessels, including *Falls of Clyde*.[9]

Falls of Clyde first arrived in Hawaii in January 1899 under the guise of her temporary Hawaiian register. The Hawaii *Herald* commented upon her arrival. "The four-masted iron ship *Falls of Clyde*, floating the Hawaiian flag...has reached Honolulu. She is the first four-masted iron ship with yards on each mast that ever came into the harbor flying the Hawaiian flag."[10] *Falls of Clyde* had been sent to obtain a permanent register. When denied, the ship nonetheless returned to San Francisco. There she was modified by Matson to carry passengers. The vessel, downrigged to a bark, sailed for Hilo on June 6, 1899. For the next eight years, *Falls of Clyde* carried assorted freight, livestock, and small numbers of passengers between San Francisco and Hilo, usually sailing on a monthly schedule. The bark returned to San Francisco laden with sugar and passengers. Typical notations of the vessel in the Hilo *Tribune* included exhortations to "all persons who intend to take passage by her...to reserve their stateroom at once as the passenger list will be a large one." On August 1, 1902, another notice announced that "*Falls of Clyde* sailed Tuesday with the following cargo: 3234 bags of Olaa sugar, 3000 bags of Hilo sugar, 5000 bags Hakalau, 11950 bags Waiakea, and 7301 bags of Pepeekeo sugar; 2 cases ribbons, 20 pkgs. household goods and 12 bags of coffee."[11]

FALLS OF CLYDE AS A SAILING OIL TANKER

In 1905, a group of 45 independent oil producers formed the Associated Oil Co. of California. Captain Matson, while a speculator in the petroleum trade, sold his shares and some real property, including one Matson steamer and four company sailers, notably *Falls of Clyde*, to Associated. The sale of the sailing ships cleared the way for steamers on the Matson Line and commenced a new career for *Falls of Clyde*. On March 26, 1907, under tow of the Matson steamer *Hilonian*, the bark left for San Francisco and conversion into a sailing oil tanker for her new owners. The use of sailing vessels in the petroleum trade was not unusual; a number of ships were converted to tanker use or specifically built for the trade.

However, most carried case oil, usually refined products, in tins packed in wooden cases and handled like any other cargo. Very few vessels were modified like *Falls of Clyde* to become bulk cargo tankers. Of all of these vessels, only *Falls of Clyde* survives. In 1907, ten large steel oil tanks were installed in her hold, steam pumps were added, and a portion of the `tween deck was left open for case oil and barrels. *Falls of Clyde* retained her bark rig. The vessel's conversion was completed early in 1908, and on February 21, 1908, the bark was re-registered with the Associated Oil Co. of San Francisco as her new owners. The vessel's capacity was 19,000 barrels, but she reportedly usually loaded only 17,500 barrels of oil in her tanks and "1,200 steel drums of 100 gallons capacity, filled with gasoline, in the `tween deck."[12]

The late Capt. Fred Klebingat, a Cape Horn sailor, master, and treasure trove of maritime lore, worked as mate aboard *Falls of Clyde* in 1916-1917. He later reminisced:

For many years the Falls of Clyde *and her running mate* Marion Chilcott *came to San Francisco only to refit. They loaded oil at an outside port near Santa Barbara, Gaviota....They loaded always for Honolulu, returning in ballast....When I joined the* Clyde *as chief mate early in 1916 the run was changed; she then traded regularly to San Francisco, loading fuel oil and gasoline in drums for Honolulu, and returning with molasses....She was a handy ship, the mate and one watch could make her do their bidding....While in the Hawaii trade she carried master, two mates, pumpman, carpenter, cook, cabin boy, and ten A.B.'s....She handled like a boat...only beating in close quarters we would have the steam up and haul the yards around....She traveled 12 knots very easily, and I have seen her logging 14 and over many a time. In the two years I was in the vessel I never saw a ship which could keep up with her.*[13]

Falls of Clyde continued in the petroleum trade between California and Hawaii, making anywhere from five to nine voyages per year until 1920. That year the bark was sold to G.W. McNear of San Francisco and fitted out for a voyage to Denmark with a cargo of case oil. Sailing from San Francisco on January 31, 1920, *Falls of Clyde* arrived at Kolding, Denmark, on June 6. Clearing for Beaumont, Texas, on June 18, the vessel arrived there on August 26 and quickly sailed for Port Arthur. Loading a cargo of Texas oil, *Falls of Clyde* sailed once again across the Atlantic, departing on September 4 and arriving at Kobenhaven on November 12, 1920. Returning to Texas in February 1921, *Falls of Clyde* was sold to new owners, the General Petroleum Co. of San Francisco, in March 1921. Under General Petroleum's flag she made one last voyage in the trade under sail, clearing for Buenos Aires by way of Tampico, Mexico, in the summer of 1921. Returning to Tampico on August 21, 1921, *Falls of Clyde* was laid up, and in December of that year was still moored in Tampico harbor.

In January 1922 *Falls of Clyde* cleared Tampico and was towed through the Panama Canal to San Pedro, California, arriving there on February 28. At San Pedro, she was stripped of her yards, topmasts, and royals, and converted into a fuel barge for General Petroleum. On March 27, 1922, under tow by the steamer *Yorba Linda*, the former bark left San Pedro for Ketchikan, Alaska, by way of Seattle. For the next 37 years, *Falls of Clyde* served as "a floating filling station in Ketchikan....securely moored to their [General Petroleum's] dock...she goes up and down with the tides, a convenient platform for servicing fishing boats in need of fuel."[14] The manager of the vessel lived aboard *Falls of Clyde* with his family in the saloon and cabins.

RESCUE AND RESTORATION

In 1959, the General Petroleum Co., reorganized as Socony-Vacuum (now Mobil Oil), developed new shore facilities at Ketchikan. *Falls of Clyde*, no longer needed, was sold to William W. Mitchell of Ketchikan, towed to Seattle, and laid up. Between 1959 and 1963 several efforts were made by Capt. Fred Klebingat, Karl Kortum, Robert Weinstein, Harold Huycke, and others to save the ship from her projected fate of being scuttled as a breakwater. In the spring of 1963, as the end of *Falls of Clyde* seemed imminent, a group of civic-minded Hawaiians, including John Wright and Robert Krauss, aided by funds from the Matson Navigation Co. and donations including money raised by school children, suceeded in purchasing *Falls of Clyde*. Towed to Hawaii by the US Navy tug *Moctobi*, *Falls of Clyde* arrived to an enthusiastic reception in Honolulu in November 1963.[15] Restoration of the vessel proceeded to the point where she was opened to the public in 1968. Remasted in 1970 and subsequently rerigged, *Falls of Clyde* was operated at Pier 5 by the Bernice P. Bishop Memorial Museum. Recently turned over to the new Hawaii Maritime Center and moved to Pier 7, *Falls of Clyde* is now the centerpiece of a major new maritime museum. Rerigged as the full-rigged ship she was when launched in 1878, restoration of the vessel continues as *Falls of Clyde* passes her 110th birthday.

APPENDIX G

NTSB Ehime Maru Accident Report

National Transportation Safety Board
Washington, D.C. 20594

Marine Accident Brief

Accident No.:	DCA-01-MM-022
Accident Type:	Collision
Time and Date:	1343 Hawaiian standard time (24-hour clock), February 9, 2001
Location:	Pacific Ocean 9 miles south of Oahu, Hawaii
Vessel Particulars:	
Name	*Ehime Maru* / *Esmeralda*
Type	Training and training vessel / Five-masted, steel-hulled, motor sailing vessel
Length	197 ft 6 in (59.8 meters) / 362 feet (110.3 meters)
Depth	12.8 feet (3.90 meters) / 32.7 feet (9.9 meters)
Beam	30 ft 6 in (9.30 meters) / 37 feet (11.27 meters)
Tonnage	499 gross tons / 6,350 net tons, 7,127 tons displacement (under normal loading conditions)
Propulsion	1 diesel engine driving 1 propeller / Steel hull, 4 masts, 4 square sails, 1 gaff sail, 1 jib sail, 1 auxiliary diesel engine driving 1 propeller
Built	1981 in Imabari Shipbuilding Co., Ltd., Ehime, Japan / 1995 in Sala Kvarnsveds Mekaniska Verkstads AB, Sala, Sweden
Owner/Operator	Ehime Prefecture, Japan / U.S. Navy
Persons on Board	Crew: 30 Students: 13 Teachers: 2 Total at least: 45	Crew: 30 Students: 11 Teachers: 2 Total at least: 43
Injuries	None / 9 fatal 1 serious, 9 minor
Vessel damage	$1.44 million / $8.5 million (total loss)
Other remarks	Recovery of *Ehime Maru* (360 million) and compensation ($2.67 million) to Ehime Prefecture for lost equipment and cadet crew salaries. Japanese response ships, coastal boats, and helicopters assisted in search and rescue operations. Japanese government provided health care for survivors, and memorial services for accident victims.

NTSB/AAR-01/01

Accident Description[1]

Route of the Ehime Maru

About 1200 local time on February 9, 2001, the Japanese training and training vessel *Ehime Maru* (figure 1), with 20 crewmembers, 13 students, and 2 teachers on board, departed pier 9 in Honolulu, Hawaii, en route to fishing grounds about 300 nautical miles south of Oahu. The area weather prediction for the day included a coastal waters forecast advising caution for the waters south of the islands from Kauai to Maui because isolated thunderstorms to the east were generating strong, gusty 15- to 20-knot winds, which, in turn, were producing waves of 8 to 12 feet.

Figure 1. The Japanese fishing vessel *Ehime Maru* built in 1998, provided batteries and engineering training to high school vocational students. (Ehime Prefecture photo)

The *Ehime Maru* was in the middle of a 74-day training voyage that had originated in Japan on January 10. During the vessel's 1-day stopover in Honolulu, its air conditioning system was repaired.

---

[1] Statements of individuals in this report are based on testimony at the Navy's court of inquiry (see http://www.dtic.mil/docs/citations/ADA396999) and interviews with Navy, Coast Guard, and other personnel conducted during the investigation in Hawaii and Japan. A video transcript was obtained from a recorder aboard the *Greeneville* during various events that led to the collision with the *Ehime Maru*.

[2] A minor Coast Guard official testified that the February 9 mission report for the two inboard fire-water pumps was 75 psi at 5 to 6 feet, the visibility was 9 miles, the air temperature was 78° F, the water temperature was 77° F, and the day was slightly overcast.

The *Ehime Maru*'s master had been a mariner for 40 years, 19 years on commercial fishing vessels and 21 years on various generations of the *Ehime Maru*. He had been a master for 8 years and the commander of the *Ehime Maru* since it was commissioned in 1996. He said that when the *Ehime Maru* left Honolulu on February 9, the vessel and its equipment were operating properly. He further stated that, in preparation for the voyage, one of the vessel's two radar sets[2] was turned on about 30 minutes before getting under way. The pilot who directed the *Ehime Maru* from the pier to the sea buoy confirmed that the vessel's radar was energized while he was on the bridge. After leaving the harbor, the radar was set to the 12-mile scale.

The master said that the *Ehime Maru* traveled at 6 knots or less for about a half hour while the crew hoisted the anchor to its stowed position. After the anchor was secured for sea, about 1250, the master activated the autopilot and the fishing vessel proceeded on a southeasterly course (166°) at 11 knots. The route of the *Ehime Maru* took it into an area designated by COMSUBPAC[3] officials for the conduct of a distinguished visitor cruise,[4] a Navy program that promotes the mission of the service by permitting civilians to observe operations on board its vessels. Various senior Navy officials described the operating location as "not a highly trafficked area" that was "about as safe as can possibly be."

The submarine selected to host the visitor cruise was the USS *Greeneville* (figure 2), which was one of five Los Angeles-class fast-attack submarines assigned to Submarine Squadron 1 of the U.S. Pacific Fleet,[5] but which had not been in the Pacific Fleet's regular rotational deployment cycle since 1998.[6]

[2] Both radar sets were model BR-3440/Mk-X59, which has 50 kilowatts of output power and operates on a 9375 megahertz (MHz) frequency (X-band).

[3] The acronym COMSUBPAC stands for an individual (the Commander, U.S. Submarine Force, Pacific) as well as the Force command office. This report refers to the person as "the COMSUBPAC" and the command office as COMSUBPAC, without the article "the." A list of all acronyms used in this report appears in appendix B.

[4] The operating area assigned by COMSUBPAC to the *Greeneville* for the distinguished visitor cruise was bounded by 21°10'N, 19°40'N, 158°00'W, and 157°00'W, which is about 58 miles wide by 75 miles long, or about 4,500 square miles.

[5] The *Greeneville* had been scheduled to begin an extended test voyage on February 9. The submarine's commanding officer (CO) agreed to conduct the cruise; however, he requested that the start of the test voyage be delayed until Monday, February 12, and that the civilian group be taken on a short trip on Friday, February 9. COMSUBPAC officials agreed, thus permitting a cruise that was contrary to Secretary of the Navy Instructions (SECNAVINST) 5720.44A, which stipulated "underway operations will not be conducted solely to accommodate guests."

[6] The *Greeneville* was pulled from the regular rotation in 1998 to be fitted with the Advanced SEAL (sea, air, land) Delivery System, which gave the submarine the operational capability to carry Navy SEAL forces and their equipment to and from hostile areas. For the next 2 years, the submarine went through underway tests and exercises of the system.

Figure 2. Photograph showing crewmembers at the top of the *Greeneville*'s sail and around a hatch on the main deck. The *Greeneville* was an "arctic-capable" submarine, meaning its sail and rudder had been strengthened to enable it to break through ice. (U.S. Navy photo)

On Board the Greeneville

Voyage Activities. The *Greeneville* had departed Pearl Harbor earlier that morning, at 0757, carrying 106 crewmembers (11 officers and 95 enlisted persons), 16 civilian visitors, and the COMSUBPAC chief of staff. At the onset of the voyage, the visitor group received a brief presentation, including a slide show, familiarizing them with the submarine's operations. The civilians were allowed to ride on the main deck and to visit the bridge inside the sail while the submarine transited the harbor, operating on the surface. They subsequently moved inside the submarine, where they were organized into two groups of eight for what the submarine's engineering officer described as the "standard ship tour." The scheduled activities for the visitors also included dining with the ship's officers and observing maneuvers, or "evolutions," which the commanding officer (CO) characterized as designed to demonstrate the submarine's capabilities.

At 0933, the "deck" and the "conn"[7] were transferred from the bridge to the control room (figure 3), where the vessel's navigator, a 34-year veteran of the Navy, was scheduled to assume the duties of officer of the deck (OOD) for the first underway watch. The OOD is a watch position that is second to the position of CO in the operational chain

[7] To have the deck means to supervise all functions and maneuvers of the ship and all personnel on watch. To have the conn means to direct the ship's movement with rudder and engine orders. To ensure safety of operations, some types of evolutions cannot be executed without the consent or approval of the CO or, in his stead, the ship's executive officer.

of command, and is responsible for directing vessel movements unless the CO assumes the conn.

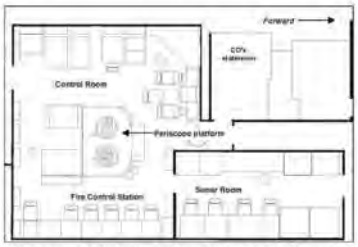

Figure 3. Plan view of the *Greeneville*'s control room, where the underway conning officer directs the ship's movements with rudder and engine orders. On the starboard side of the control room is the fire control station, where the fire control technician of the watch (FTOW) determines "solutions" for the range, course, and speed of "contacts," or other vessels, detected by the sonar system, which is in a separate space forward of the control room. The conning officer, the FTOW, and the sonar supervisor compose the primary members of the submarine's contact management team.

At 1017, the *Greeneville* submerged within its assigned operating area about 18 miles southeast of Pearl Harbor. The OOD testified that as the *Greeneville* submerged and dived to a depth of 150 feet, several civilian visitors were seated at "significant control stations." The OOD said, "We didn't have any specific track to follow," and that the submarine just drove north to south. He said that "[we] didn't want to get too far away from Pearl [Harbor]." He further stated that the plan of the day (table 1), a schedule listing the events and the evolutions established for the cruise, was "fairly tight," without "a lot of time to mess around."

The plan of the day called for lunch to begin at 1100 and end at 1200. The distinguished visitors were to eat in the officers' dining room (wardroom); however, because the wardroom was too small to seat the visitors as one group, they were divided into two groups, and two lunch periods were scheduled to allow them time to dine and be finished before the evolutions were scheduled to begin at 1230. The first group of civilian

visitors, joined by the CO, went to lunch at 1045, while the second group of civilians visited the control room and the sonar room.

Table 1. *Greeneville*'s plan of the day for February 9, 2001

Time	Scheduled Event
0230	Reactor startup brief
0300	Reactor startup
0400-0530	Breakfast
0430	Reveille
0500	All hands muster
0545-0645	All hands clean up ship FWD [forward]
0700	Maneuvering watch personnel man the bridge
0715	Station the maneuvering watch
0800	Underway for VIP [distinguished visitor] cruise
1000	Dive
1030	Deep dive
1100-1200	Lunch
1130	Relieve the watch [second underway watch relieves first underway watch]
1230	Angles [depth-change maneuvers involving steep angles, frequently at high speeds, called "angles and dangles" by crew]
1300	EMBT [emergency main ballast tank] blow
1330	Station the maneuvering watch
1400	PIH [ocean point south of the channel entrance to Pearl Harbor]
1500	Moor/return to port

NOTE: Table does not show crewmen's section of the plan, which includes names of crewmen serving in a training capacity during cruise. "Watch" refers to a time period in which a crewmember is assigned to a given duty.

While the civilians were in the sonar room, the crewmembers put the sonar system recorder in the play mode so that the guests could listen to tapes of marine life sounds typically heard underwater.[8] Shortly thereafter, in the control room, the OOD ordered the crew to "rig for deep submergence," and, at 1054, the *Greeneville* submerged to a depth of 700 feet.

After reporting to the CO that conditions were "normal," the OOD ordered the submarine to a classified depth for about a half hour while some visitors were still in the control room. During this time, the crewmembers collected and bottled water samples from the ocean, which were labeled with the classified depth and given to the visitors as souvenirs. At 1134, the OOD brought the vessel up to a depth of 650 feet.

[8] The sonar supervisor said that the crew forgot to reset the recorder before the evolutions began; therefore, the audio received by the sonar system was not captured on tape.

Watch Change. The plan of the day indicated that the second underway watch relieved the first underway watch at 1130. Shortly after 1130, the main propulsion assistant entered the control room to prepare for his duty assignment as the OOD of the second underway watch. The main propulsion assistant had about 6 years of service in the Navy, and the *Greeneville* was his first sea tour. He had reported to the vessel in March 1999 and begun a qualification program for various onboard duty assignments. He had qualified as an underway OOD about 6 months before this distinguished visitor cruise; however, during this time, the *Greeneville* was in the shipyard for 4 months, from September through December 2000. (This officer is referred to as the OOD-2 in this report.)

The OOD-2 said that he learned the Analog-Video Signal Display Unit (figure 4), or AVSDU, was not working when he reported to the control room for his watch. The AVSDU duplicated the contact data displayed on the monitors in the sonar room and permitted the conning officer to observe the vessels being tracked without leaving the control room. The navigator had noted that the AVSDU was inoperable and had reported its status to the CO before the *Greeneville* had sailed that morning; however, the malfunction of the sonar repeater did not meet the criteria for a significant equipment casualty that would have precluded the submarine from sailing.[9]

Figure 4. The Analog-Video Signal Display Unit, or AVSDU, was a sonar repeater installed near the Greeneville's periscope platform. On the day of the accident, the AVSDU was not working. (U.S. Navy photo)

The OOD-2 stated that, as part of his status briefing, the OOD of the first underway reminded him that to compensate for the loss of the AVSDU, he needed to "periodically go into sonar to assay the contact picture."

[9] See *Operational Reports*, Naval Warfare Publication 10-1-10 (Chief of Naval Operations, Washington, DC: 1987).

The first underway OOD said that he observed his watch relief as he did "a normal prewatch tour." The OOD-2 went into sonar and talked to the sonar supervisor to get an idea of what the contacts were. The OOD-2 next reviewed the monitors at the fire control system station "for a little while" and then went over to the chart table to verify the submarine's position and to check the plot to ensure "we were where we should be."

The OOD-2 recalled that when he took over the conn, at 1143, the *Greeneville* was "driving south" at a speed of 10 knots and a depth of 650 feet. He contacted the CO to obtain permission to allow crewmembers in the torpedo room to fire slugs of water from the torpedo tubes while the visitors in the area watched. To give the civilians a sense of how the ship drove, he permitted some of them to sit at the controls under the oversight of qualified technicians while he ordered simple course and depth changes.

About the same time, the first lunch sitting was ending. The CO testified that the lunch period was his first opportunity to talk with the guests. The CO had almost 20 years of service with the Navy and had been assigned the command of the *Greeneville* in March 1999. He said that the visitors were from his home state and as a result of his conversations with them, the first lunch sitting "ran a little long." At 1145, the second group of visitors went to lunch, which was hosted by the submarine's second in command, the executive officer (XO), a 15-year Navy veteran who had served on the *Greeneville* as XO since 2000.

About 1207, the OOD–2 ordered a course change to north to begin the return to the northern part of the *Greeneville*'s assigned operating area. Shortly before 1230, as the *Greeneville* was proceeding on a due-north course of 000°,[10] the sonar system (figure 5) began tracking a contact, bearing 331.2°, which the crew designated S-12.[11] Three crewmen were on duty in the sonar room: the sonar supervisor, a sonar technician at the broadband[12] "stack," or workstation, and a workload share stack operator.

The sonar supervisor had 7 years of Navy service, including 4 years as a qualified sonar supervisor (3 years on the *Greeneville* and 1 year on his previous submarine). He had been assigned to the *Greeneville* in 1997. The broadband stack operator, who had primary responsibility for detecting and tracking sonar contacts, had been in the Navy for 1 1/2 years and had been qualified to stand sonar watch for over a year. The workload share operator, who was responsible for maintaining the sonar log and providing backup to the broadband operator, had been in the Navy about a year and on board the *Greeneville* for 6 months. He had not yet qualified to stand watch in sonar; therefore, he was considered an "under-instruction" operator.

[10] All bearings are based on true north.

[11] When sonar gains a vessel contact, it is assigned a letter and number designation, such as S-1. The letter "S" stands for sonar and is pronounced using the military phonetic alphabet for S, which is Sierra. The number represents the order in which the vessel is detected.

[12] Broadband refers to a wide range of sound frequencies. The broadband monitor is a visual display of all sound waves around a submarine.

Figure 5. Each sonar workstation, or stack, had two monitors. The two stacks at right displayed system input from hull-mounted arrays. (U.S. Navy photo)

About 1232, sonar gained a new contact (the *Ehime Maru*), bearing 358°, or almost due north. The crew designated the contact S-13. The sonar supervisor assessed it to be a "distant" contact.[13] Reconstructed data show that, at this time, the *Ehime Maru* was about 20 nautical miles away.

According to the sonar supervisor, the acoustic environment was good, and contacts could be heard from a distance of 15 to 20 nautical miles. He said that, as sonar supervisor, he looked for "something with a very high bearing rate, something that may be on our left side drawing right, or right side drawing left," which could represent a "closing" situation (meaning the target is heading toward the submarine). He said that when sonar first gained S-12 and S-13 (the *Ehime Maru*), "they did not have much of a bearing rate."

The sonar system was integrated into the fire control system and relayed bearing data on the contacts held, which was then displayed in four different formats on the fire control monitors. (See figure 6.) The FTOW, the technician manning the watch station, was a 14-year Navy veteran who had been involved in operating fire control equipment 12 of his 14 years in submarines. His work involved performing "target motion analysis"[14] (TMA) of the contacts being tracked by sonar, meaning he was responsible for determining the course, speed, and range of surface and submerged vessels (or

[13] At the Navy court of inquiry, sonar officials testified that for a contact to be considered distant, it is 20,000 yards or more away.

[14] The Navy also refers to target motion analysis as contact motion analysis in some documents.

targets) potentially posing a threat to the submarine. He accomplished TMA by adjusting the knobs at his station monitors to enter estimates for course, speed, and range variables into the fire control system computer and iteratively resolve the motion of the sonar contact relative to the position of the "own ship" (the submarine).

Figure 6. The four display screens at the fire control station, looking left to right, are (1) time-of-sight, (2) time-bearing, (3) TMA, and (4) op-summary. (U.S. Navy photo)

The FTOW said that he followed his usual procedure to determine a solution for S-13 and other contacts, based on the information relayed to him when the sonar system initially gained a contact. He indicated that sonar did not designate any of the contacts as merchant ships. He stated that "just being in Hawaiian waters," he assumed that the contacts were typical of the "traffic around here . . . probably trawlers, fishing vessels [and] pleasure crafts."

The FTOW told Safety Board investigators, "I always put in a closing solution, which means the contact . . . is pointing at us, coming at us . . . and anywhere between 5 and 15 knots" depending on whether the contact is a trawler or a merchant ship. He added that he always initially entered a conservative range, "usually anywhere between 8,000 and 10,000 yards."

He said that if the contact had a low or steady bearing rate, "you assume that he's closing." He also stated that the fire control system needed several bearing rate changes to refine a solution, which he obtained when the submarine changed course, as it did

about 1240, when the OOD-2 ordered a baffle clear.[15] The *Greeneville* then resumed a northerly course, which it maintained until about 1310.

Fire control data, as reconstructed by the Navy, show that after the bearing data for S-13 were relayed from the sonar system to the fire control system (at 1232:59), the FTOW entered three closing solutions between 1233:14 and 1240:00. While the FTOW was calculating these early solutions for S-13, the *Ehime Maru* was moving at 6 knots while stowing anchor. The FTOW next entered a closing solution about 16 minutes later, at 1256:00. Then, about 1258, he changed the course for S-13 from closing to "opening," that is, heading away from the submarine.

The FTOW stated that, on the day of the accident, he never tracked more than two or three contacts, which was a light workload. He indicated that, in the past, he had tracked as many as 20 to 30 contacts in high-traffic areas and that on more than one occasion, he had worked with another fire control technician at his station to track more than 40 contacts at a time.

After the second visitor lunch ended, about 1245, the XO went to the CO's stateroom to report that the mess (kitchen and dining areas) would be secured within 5 minutes and to suggest that the ship then begin the angles evolutions, which had been scheduled on the plan of the day for 1230. The CO asked who had the helm and, upon learning that a less experienced helmsman was on duty, directed the XO to replace him with a more experienced helmsman for the high-speed evolutions. The CO then stayed in his stateroom, signing photographs to give as mementos to the civilian guests, while the XO left to join the other crewmembers in the control room.

The OOD-2 told investigators that, shortly before 1300, he realized that, given the position of the submarine, about 17 miles from the unmarked seaward entrance to Pearl Harbor (designated P/H[16]), and the activities listed on the plan of the day, the submarine would be late returning to P/H. The OOD-2 expressed his concerns about returning on time to the vessel navigator, who had returned to the control room after lunch because he wanted to oversee the navigation watchstanders while the submarine performed some of the high-speed evolutions. The navigator later told investigators that he determined the submarine was about 10 or 12 miles from P/H. The navigator said if the submarine had surfaced at that time and driven toward P/H, the *Greeneville* would have arrived there on time. He knew, however, that the CO wanted to do evolutions so he approached the XO and reminded him of the time and the need to get back to P/H by 1400.

The XO then returned to the CO's stateroom to advise him that they had less than an hour before the vessel was due back at P/H. The XO testified that the CO said he

[15] As is typical of all submarines, interference from noises generated by the *Greeneville* itself prevented the sonar system from reliably detecting sonar signals between approximately 120° and 240° relative to the vessel's bow. This arc astern of the vessel is known as the "baffles" area, and a submarine has to periodically alter course to uncover this null area, or "clear the baffles," for the sonar system.

[16] P/H is located at 21°19'17" N, 157°56'38" W, about 6 miles from the northern edge of the *Greeneville*'s assigned operating area on the day of the accident.

would finish signing the photographs for the visitors and remarked, "Well, I guess we are going to be late." Soon after, the navigator went to the CO's stateroom to remind him that the submarine was due back at 1400.

The navigator said that as the CO left his stateroom, he said that he was going "to push the OOD[-2]." The quartermaster[17] indicated that he was present when the navigator questioned whether the *Greeneville* would be able to complete all the planned evolutions and make it back to P/H on time. He stated, "We talked it over with the XO and CO and they thought we could."

The OOD-2 told Safety Board investigators that no senior officer, including the navigator, the XO, or the CO, discussed with him whether or how the plan of events might be changed or evolutions curtailed to avoid being late. He testified that he assumed that some evolutions would be canceled. The OOD-2 stated that the submarine was about 5 miles from the edge of its assigned submerged operating area, and that he was concerned about doing high-speed maneuvers near the edge of the operating area. He further stated that he could not remember whether he voiced his concerns to the officers.

All Visitors Called to Control Room. The XO made an announcement on the public address system inviting all guests to the control room to observe the conduct of the evolutions. The OOD-2 said that before the visitor group gathered in the control room, sonar had been tracking three surface vessels: S-10 to the south and S-12 and S-13 (the *Ehime Maru*) to the north. The OOD-2 said, "We did not have a great contact picture of where they [the contacts] were." At 1245:45, S-10 had "faded," meaning it no longer was being tracked by sonar. The OOD-2 did not order course changes for TMA to improve contact awareness for S-12 and S-13 before the XO invited the guests to the control room.

The COMSUBPAC chief of staff and 15 of the 16 civilian visitors[18] entered the control room about 1310, or about 10 minutes after the scheduled time for the last evolution on the plan of the day. Several visitors then went into the sonar room (figure 7).

Meanwhile, the CO testified that, after exiting his stateroom, he went into sonar to assay the contact picture. He said that he reviewed the sonar display of the contacts with the sonar supervisor, who advised him of two contacts, a merchant vessel to the northwest (S-12) and a surface craft to the north (S-13, the *Ehime Maru*). According to the CO, the sonar supervisor told him that the contacts "were distant, [and] up by land." The sonar supervisor told investigators that he assumed the contacts were more than 10,000 yards away. He said that he based his assumption on three factors—the bearing rate of the contacts was still small, the signal-to-noise ratio (SNR) was relatively low (SNR is a measure of signal strength relative to background noise), and the other sound characteristics indicated that the contacts were probably more distant than close.

[17] The quartermaster on watch plots the vessel's position on a navigation chart and makes course recommendations to the conning officer. He also maintains the deck log.

[18] One of the civilians became seasick and was resting in a stateroom.

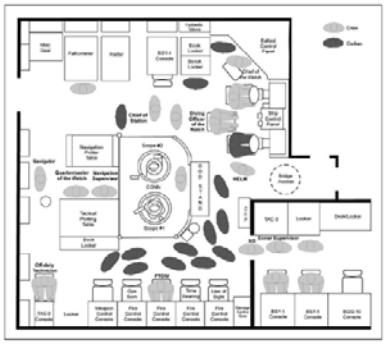

Figure 7. When the *Greeneville* crew began high-speed maneuvers to demonstrate the capability of the submarine to the visitors, 33 people, including crew and civilians, were in the control room and the sonar room. This illustration shows the approximate location of the civilians when the submarine executed the last evolution, an emergency surfacing maneuver.

About 1314, the CO entered the control room and advised the OOD-2 to prepare the submarine to perform the angles and dangles maneuvers. He did not discuss the contacts with the OOD-2 when he returned to the control room. He said that, based on his prior experience overseeing the main propulsion assistant while he operated as an OOD, he was confident that the officer had maintained situational awareness, that is, knew where the submarine was in respect to the contacts. At the Navy's court of inquiry, senior officers and enlisted personnel stated that, as an OOD, the main propulsion assistant had a reputation for being methodical, meticulous, and "not easily pushed." They also indicated that he typically took longer than more experienced OODs to accomplish tasks.

The CO said that the OOD-2 acknowledged his instructions. He further stated,

> I didn't focus on [the OOD-2's] actions. I can't tell you if he did not exit the conn and enter the sonar room, which would have been customary for him to do prior to the conduct of those evolutions. I . . . was looking elsewhere. I was walking around the control room to enhance my situational awareness, my understanding of the contact pictures, looking over . . . to see what we had on time/bearing displays, to see what the Fire Control Technician of the Watch . . . was doing, and looking and engaging the Quartermaster as to our current ship's position to help me understand what our situational awareness was because I had lost it while [I was] in the dining room and . . . stateroom.

The CO testified that he looked at the ops-summary display at the fire control station, which shows the position of all contacts with respect to the position of the submarine. However, he said he did not notice which time history the FTOW had selected for the display, and if a short time history had been selected, the display would not have shown that the OOD-2 had ordered only two course changes (the baffle clear at 1240 and the course change to north at 1245). The CO also stated that he did not look at the plot maintained by the navigation watchstanders. He said if he had done so, he would have realized that the OOD-2 had driven the boat only in a northerly direction and had not driven in easterly or westerly directions that might have provided an accurate contact picture.

Witnesses stated that the CO chatted with the civilians, advising them of the best locations in the control room to observe the maneuvers. Three of the civilians stood on the periscope platform. The FTOW stated that about six or eight visitors stood around the fire control station, blocking his access to the contact evaluation plot (CEP), a large paper graph that was mounted on the bulkhead forward of the periscope stand. The FTOW was required to annotate the CEP with the submarine's heading, the sonar contacts' bearings, and other pertinent observations to provide the OOD with a display of the submarine's position in relation to the known vessel contacts.[19]

Some of the civilians stood in front of the forwardmost two fire control system displays, which the OOD-2 said he typically used to monitor the contact situation. The OOD-2 later told Safety Board investigators, "I didn't have free access all the way over there. I got close enough where I could look at the contact picture and . . . the fire control screens." (See figure 6.) The CO said that when he went to the control room and reviewed the fire control system consoles, the visitors blocked his view of the CEP.

Several crewmembers stated that equipment preparations needed to support higher speed maneuvers delayed the start of the evolutions. According to the OOD-2, the CO "seemed frustrated that he couldn't start the maneuvers right away."

[19] The *Greeneville* was among the last Navy submarines to be equipped with an automated CEP and did not have one at the time of the accident. All Navy submarines now have automated CEPs that display data for both the submarine and its contacts. Navy officials who examined the *Greeneville* CEP after the accident described the entries made by the FTOW as "very sparse," stating, "There were essentially no contact entries for the hour leading into the collision."

"Angles and Dangles" Begin. At 1315, the CO ordered the *Greeneville*'s speed increased to 14 knots. The OOD-2 stated that for the angles maneuvers—steep angled depth changes, frequently at high speeds—a CO typically gives an OOD the boundaries of where to operate, such as "stay between these two depths" and "change course using this high an angle," and then allows the OOD to choose the course of action. Both the OOD-2 and the CO stated that, in this instance, the CO stood immediately behind the OOD-2 and ordered the specific course, speeds, and depths that he desired, and the OOD-2 merely repeated the orders to the diving officer and the helmsman.

The OOD-2 said that the CO directed him to order angles up to 30° and depth changes from 650 feet to 150 feet at speeds varying between 10 and 15 knots. The FTOW testified that the "captain was driving the whole evolution," and the "OOD[-2] was a mouthpiece." While the ship was going through the evolutions, the CO gave the civilian visitors a running commentary on the maneuvers.

According to the FTOW's testimony, during the angles and dangles, he was able to track contacts S-12 and S-13 (the *Ehime Maru*) but not "100 percent . . . the whole time." According to system data, the solution variables for S-13 were not changed for 23 minutes, between 1314 and 1337, while the submarine executed first the angle evolutions and then the high-speed turns.

The FTOW said that because the civilian visitors blocked his access to the CEP and because "you really couldn't do anything" during the high-speed maneuvers, he stopped maintaining the CEP. He told Safety Board investigators that he did not advise anyone that he had stopped annotating the CEP and, because no one mentioned the plot, he thought that no one noticed that he was not maintaining it.[20] He later told Safety Board investigators that he had been the FTOW on numerous visitor cruises on the *Greeneville* and other submarines in the past and had never maintained the CEP while civilians were in the control room.

About the time of the angles and dangles, a sonar technician who had served on the first watch returned to the sonar room to get his jacket. He testified that several civilian guests were in the sonar room, in addition to the sonar supervisor, the broadband stack operator, and the workload share stack operator. The off-duty sonar technician was a 12-year Navy veteran who had joined the *Greeneville* crew in 2001. He said that he noticed that the sonar supervisor and the sonar technicians were trying to talk to each other and the guests at the same time.

The sonar supervisor asked that the off-watch sonar technician stand by the under-instruction operator on the workload share stack because having "another set of eyes . . . can't hurt." The sonar supervisor later testified that he asked the off-watch sonar technician to stay because the under-instruction operator had not completed the sonar qualification requirements, not because the sonar operator at the broadband monitor was

[20] A submarine force operations order (OPORD) stipulates that the FTOW cannot cease maintaining the CEP without permission from the conn.

overloaded. He did not brief the off-watch sonar technician about the contacts that sonar held at that time.

The off-watch sonar technician said that the sonar operator at the broadband stack appeared not to be distracted by questions from the guests. The unqualified workload share stack operator, however, was trying to answer the visitors' questions. At one point, the workload share stack operator started to turn away from the display to talk with the guests, but the off-watch technician told him not to do so. The technician said that he then asked the visitors to leave the sonar room.

The off-watch sonar technician said that during the angles and dangles, he became concerned about an "interference pattern" on the sonar monitor that appeared to suggest that one of the contacts was closing. He expressed his concern to the sonar supervisor, who told him to check to see what data the FTOW had on the contact. Shortly thereafter, the off-watch sonar technician went into the control room and asked the FTOW about "S-10," stating that it appeared to be a close contact. The FTOW said that he made some adjustments on the fire control system to try to put the contact on a closing course, but "it wouldn't fit," and he advised the off-watch sonar technician that the contact was on an opening course.[21]

Begin High-Speed Turns. About 1325, the CO directed the OOD-2 to order a course change to 140°, and the *Greeneville* began executing high-speed turns. According to the sonar supervisor, moving back and forth numerous times "just makes your display [look like] spaghetti. You've got lines in all directions from how the ship's driving. Contacts are kind of fading in and out" as they enter and leave the baffle area. Both S-12 and S-13 faded as they entered the port baffles.

To obtain accurate TMA results, the conning officer is responsible for ordering the submarine on a constant course, speed, and depth for a period of observation known as a "leg," during which the relative motion of the contacts can be observed. According to Navy officials, a minimum of two legs is necessary to determine the solution for a contact, and maneuvers that afford looking at the target from different aspects "very quickly" reduce the possible solutions to "a very limited number."

Shortly before 1331, after the high-speed maneuvers were completed, the CO ordered a speed reduction, a decrease in depth, and a course change to 340°. The CO's Standing Order 6 stipulated that the submarine would be held on course a minimum of 3 minutes to allow sonar and fire control to obtain an accurate contact picture.[22] According to recorded data, the submarine remained on the 340° course for 91 seconds. Of this time,

[21] System data show that the *Greeneville* lost the track on S-10 more than 30 minutes earlier, about 1245. The Navy court of inquiry concluded that the off-watch sonar technician confused his contact numbers and that based on his observation that the close contact later faded in the baffles during the course turn to 120°, was referring to S-12.

[22] Submarine COs develop standing orders for vessel operating requirements that are based on instructions issued by the Navy's submarine forces commanders. The fleet instructions state that commanding officers "retain the flexibility to adapt/edit their standing orders as long as they meet the core requirements." The 3-minute course standard for TMA is set out in Naval Warfare Publication 3-21.51.1.

the total period that the *Greeneville* maintained a steady depth and speed was about 20 seconds.

Order to Periscope Depth. At 1331, the CO ordered the ship to slow to 10 knots and directed the OOD-2 to make preparations to proceed to periscope depth and to be at that depth within 5 minutes.[23] Figure 8 shows key events, beginning at 1331, on the *Greeneville* relative to the tracks of the submarine and the *Ehime Maru*.

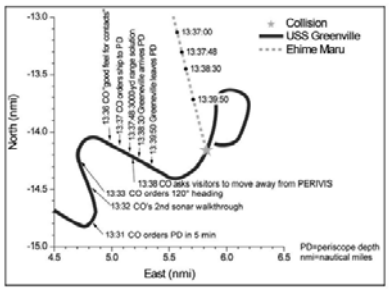

Figure 8. Plot showing the tracks of the *Greeneville* and the *Ehime Maru*. The *Greeneville* track is annotated with key events on the submarine beginning at 1331. The *Ehime Maru* track is annotated with the position of the fishing vessel at some corresponding times.

The CO's Standing Order 6 lists 16 actions and instrument checks, some involving as many as six steps, that the OOD is required to perform when preparing to go to periscope depth. One required action is for the OOD to conduct a periscope-depth briefing with key personnel to verify the contact picture. The CO later told Safety Board investigators,

[23] The CO's own standing orders stipulated that no less than 8 minutes would be allotted for the preparations necessary to go to periscope depth.

> He [the OOD-2] was so . . . slow, I knew that he couldn't get to PD [periscope depth] in 5 minutes. It was my objective to give him a goal to work towards . . . I doubt that any of my experienced officers of the deck could have gotten to periscope depth in 5 minutes.

The OOD-2 stated that when he heard the CO order him to prepare to go to periscope depth in 5 minutes, he considered the directive "unusual" and was concerned about the time limit. He said that when preparing to go to periscope depth, the OOD drives the ship "a certain way . . . so he can get a clear contact picture." To ensure the accuracy of the information, he asks sonar to report all contacts. If the reliability of the data is questionable, the sonar supervisor can advise a good course for TMA, whereupon the OOD orders more maneuvers.

The OOD-2 said that he then reports to the CO explaining the contact picture, including the types of contacts and their bearings, speed, and drift. The CO evaluates the OOD's report and, if convinced that the information is accurate, grants the OOD permission to proceed to periscope depth.

The OOD-2 said that he did not have a periscope-depth briefing because of "the time constraints and the challenge to go to periscope depth rapidly." He further stated,

> I would never think of not doing a periscope brief but, at the time, I had the commanding officer present, the executive officer present, other department heads present, as well as the chief of staff, SUBPAC.

Regarding the actions of the CO, the OOD-2 stated,

> Here's a man with much more experience than I have, much more schooling than I have, [who] can much more rapidly assess and evaluate information . . . I did not believe that he was putting the ship in an unsafe position, and [thought that] . . . the contact picture allowed for safe periscope depth.

Regarding his orders to quickly complete the steps necessary to bring the vessel to periscope depth in less time than indicated in his standing orders, the CO later testified, "I chose to not follow specific things out of my standing orders because I deemed at that time them not to be necessary."

Signal-to-Noise Ratio Increase. Meanwhile, in the sonar room, the broadband stack operator noted that while the submarine was in the middle of the high-speed maneuvers, the SNR for S-13 was "relatively high." Figure 9 shows the SNR data for S-13 (the *Ehime Maru*) that were captured by the *Greeneville*'s sonar system computers on the day of the collision, as plotted by Safety Board engineers.

At this time, the off-watch sonar technician who had been assisting the technicians at the stacks was in the control room, talking with the FTOW. The broadband operator said that he reported the SNR increase on S-13 to the sonar supervisor,

whereupon the sonar supervisor "went to the curtain in control."[24] The sonar technician said that he did not know whether the sonar supervisor spoke to anyone about the SNR increase. When asked about the broadband operator's report, the sonar supervisor said that he did not recall being told about the SNR increase.

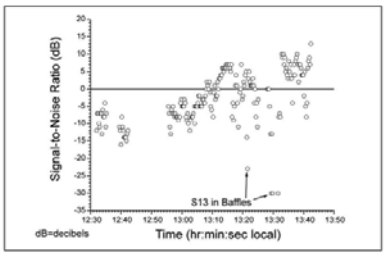

Figure 9. An increase in the SNR for a contact can be an indication that the target is getting closer. In this plot, each circle represents an S-13 signal captured by the *Greeneville*'s sonar system. As indicated in the plot, the SNR for the *Ehime Maru* increased over time except for when the fishing vessel was briefly in the baffle area. Note: The plot developed by Safety Board engineers is not representative of the display on the sonar monitors.

After giving the OOD-2 the order to go to periscope depth, the CO briefly went into his stateroom. From there, he went to the sonar room to assay the sonar picture and "obtain contact awareness." The CO said that as the ship was coming to a keel depth of 150 feet, he overheard the broadband operator tell the sonar supervisor that they had regained "previously held contacts." Recorder data indicate that while the CO was in sonar, the operators regained two contacts, S-12 at 1332:03 and S-13 (the *Ehime Maru*) at 1332:48. According to the sonar supervisor, he did not recall discussing any contacts with the CO while he was in the sonar room.

In the meantime, the XO told the OOD-2 that he would help him determine a course for proceeding to periscope depth by going into the sonar room to get the contacts.

[24] The aft door of the sonar room had a curtain to block the light from the control room.

The XO later stated that he did so because the AVSDU was not operating. The XO went forward in the corridor and entered the sonar room through its forward door.

As the XO entered the sonar area, the CO was exiting the aft sonar door to go into the control room. About that time, the off-duty sonar technician reentered the sonar room after his conversation with the FTOW. He discussed his concerns with the XO, stating that he did not think he was wrong about the closing contact. The XO checked the fire control screens in the control room, returned to sonar, and asked the off-duty sonar technician how fast the *Greeneville* was operating. The off-duty sonar technician said that he then realized the submarine itself had caused the interference pattern because of the speed it was traveling. He further stated that his suspicions were confirmed when the submarine slowed and the interference pattern went away.

When the CO reentered the control room, he looked at the first monitor, the line-of-sight display, at the fire control station. The CO later told the Safety Board that, at this time (1333), he did not think the contact picture had changed, meaning sonar was holding two contacts. He stated, "I was confident that those contacts remained close along the Oahu coast, operating in that vicinity." He said, "I didn't pick up on the fact . . . that we had driven on north-south legs," meaning the *Greeneville* had not executed turns that would have provided changes in bearing rates.

Upon returning to the conn, the CO ordered a course change to 120° for the *Greeneville* to clear baffles. Concurrently, he announced to the visitors that the purpose of a baffle clear was to allow sonar to check for hidden contacts and prevent a collision at periscope depth. The OOD-2 stated,

> I was a little surprised when . . . the captain directed me to change course. I felt that he . . . was kind of driving the ship at that point . . . He had been kind of driving the ship before then, during the angles and dangles, when he gave me the courses and depths and speeds he wanted to drive.

During the course change, sonar gained a new contact, S-14. The fire control system displayed the automatic first solution for S-14 at 1334:03. The FTOW subsequently determined only one tracking solution for S-14, which he entered into the fire control system at 1334:48.

When the XO entered the sonar room, he positioned himself behind the sonar technicians, looking at the sonar display monitors. The sonar supervisor said that he assumed that the XO had come into sonar because the AVSDU was not working. He further stated that he did not discuss the contact picture with the XO. The XO later told Safety Board investigators that, while in sonar, he observed three contacts. He then stood in the sonar room's aft doorway while the submarine went to periscope depth. He did not give the OOD-2 or the CO any information about the sonar contacts or recommend any course for surfacing.

Shortly after sonar gained contact S-14, the signal for contact S-12 faded in the port baffles. About 1335, the baffle clear was completed, and the submarine was steady

on course 120°. Reconstructed system data show that, about this time, the *Ehime Maru* (contact S-13), operating at a constant heading of 166° and a speed of 11 knots, was 3,282 yards from the submarine. When the submarine steadied course, the FTOW was able to resume determining solutions for the contacts. The FTOW said that he had "very low" confidence in his track for S-14 because it was based on "a single leg" that had lasted about a minute.

At 1335:39, the OOD-2 announced on the public address system for the crew to report all contacts. The CO testified that he recalled the sonar supervisor reporting two contacts, S-13 and S-14. The FTOW stated that he recalled sonar reporting three contacts: S-12, S-13, and S-14. About that time, the CO announced that he had "a good feel for the [sonar] contacts." According to the FTOW, the fact that the sonar announcement included S-14 and the CO's statement reassured him that the CO was aware of S-14.

About 1337, about 1 1/2 minutes after the *Greeneville* was on a steady 120° leg, the CO ordered the OOD-2 to proceed to a depth of 60 feet (periscope depth). Reconstructed system data show that, at 1337:00, the *Ehime Maru* was at a range of 2,724 yards, or 1.34 nautical miles. (See figure 8.) The FTOW stated that he quickly updated the solutions for the contacts that he was tracking, including S-12, S-13, and S-14. He described his updating as "rushed" and said that he was still updating his contacts as the submarine ascended to periscope depth. He said that he continued to give priority to analyzing S-14 because of the lack of data on the contact.

The sonar supervisor stated that when the submarine ascended to periscope depth, the monitor displays were changed to a different scale to enable the crew to watch for transient noise that was "different" or "unexpected," such as a quick change in a contact's bearing rate. The FTOW stated that while the submarine proceeded to periscope depth, he monitored the three contacts on the fire control system's time-bearing presentation because a fast bearing rate would indicate a close contact. System data indicate that, at 1337:48, less than a minute before the submarine arrived at periscope depth, the FTOW updated the solution for S-13 (the *Ehime Maru*), changing it from an opening to a closing solution and adjusting the range from 16,000 to 4,000 yards. The dots on the display immediately began to align, an indication that the solution was comparatively accurate. Reconstructed system data show that, at 1337:48, the *Ehime Maru* was at a range of 2,510 yards, or 1.24 nautical miles. (See figure 8.) The FTOW said that he failed to notice the range of S-13 "because he was trying to get everything done" before the submarine reached periscope depth. Standing Order 6 stipulated that the FTOW would notify the conn of all contacts 4,000 yards or less from the *Greeneville*, however, in this case, the FTOW did not report the status of S-13 to either the OOD-2 or the CO.

As the *Greeneville* ascended to periscope depth, the CO asked that some of the civilian visitors move because they were blocking the view of a video monitor that displayed the image seen through the periscope.[25] At 1338:30, the ship arrived at a depth

[25] The periscope video system, or PERIVIS, displayed the periscope image on several monitors throughout the vessel, including a screen near the fire control station. The PERIVIS also had a record feature that could be activated by the person using the periscope.

of 60 feet. Reconstructed system data show that, at this time, the *Ehime Maru* was at a range of 2,315 yards, or 1.14 nautical miles. (See figure 8.)

Periscope Search. The OOD-2 said that when the submarine reached periscope depth, he started to conduct a normal search using the No. 2 periscope.[26] When the periscope broke the water's surface, he executed the rapid low-power searches. He said that he completed his three rapid revolutions and announced, "No close contacts." He said that he was about to begin his next search when the CO took the periscope and began his own search routine. The FTOW said that, in accordance with the usual procedures, no one said anything in the control room or made any reports until they heard the OOD-2 say, "No close contacts," after the initial phase of his periscope search.

The CO later testified that he searched primarily in the sector where he believed the known contacts were located. He stated that he

> swept the scope in low power, went to high power, looked, then panned to the right, saw the island [Oahu] . . . I can only see the mountain peak, I can't see the mountains . . . because of this white haze . . . Then I could see an airplane taking off. . . . I panned to the right where I thought I would see [S-13] the *Ehime Maru*. I looked over at the remote repeater [own-ship's data] and I saw the numbers and [thought] that looks right. That's where the guy is. Didn't see him. Then went to low power and then turned to the right. I think . . . the *Ehime Maru* was perhaps further to the right, and as I swept in low power . . . missed her. And that's the only explanation that I can think of as to why I missed the vessel. It was perhaps too far to the right out of my field of view when I was doing my high power search thinking that the degree of optics that I was covering would encompass and overlap that area of uncertainty.

The FTOW said that when the periscope projected above the water, he shifted his attention to the PERIVIS monitor. He said that the CO did a "quick 360-degree look" in the general direction of the contacts, 40° and 340°, and then stopped on 18°. The CO next ordered the ship "to come up for a high look," a depth of 58 feet, to increase the periscope height of eye. The FTOW described the CO's search as "uncued" because he did not ask fire control to verify the bearings to the contacts, "which is my job." The FTOW stated, however, that he "was confident that the captain knew what he was doing during the periscope search."

The FTOW said that he thought that he had a good range for S-13, and that it was between 5,000 to 6,000 yards while the submarine was at periscope depth. He was under the impression that, of the three contacts, S-14 was the closest. He said, however, that he

[26] Naval Warfare Publication 3-13.10 requires making at least three 360° low-power sweeps, about 8 seconds per sweep, to search for close contacts as soon as the periscope breaks the surface. If safe operation is indicated, "No close contacts" is announced. The *Greenville*'s former CO, in describing a standard periscope search, testified that after the initial three sweeps, the OOD would do an air search in which he panned from the maximum elevation view down to the horizon, then would announce, "No airborne contacts." He would then do a 360° low-power search, which took about 45 seconds, followed by a 90° high-power sector search on the point where he terminated the 360° low-power search.

was not surprised when he didn't see a vessel on the PERIVIS because "fire control [is] only as good as the maneuvers you make," and he had "range errors . . . more than 50 percent of the time." He said that he estimated that he might be off by about 2,000 yards for S-13. He said that his confidence in the solutions for the contacts "immediately rose up" when they did not see any vessel through the periscope.

ESM Search. In addition to the periscope search, the movement to periscope depth enabled the technicians at the electronic support measures (ESM) system, located in a separate room behind the control room, to conduct a defensive search to identify and classify sources of detected electromagnetic radiation. Two crewmembers, a qualified and an under-instruction ESM operator, were present in the ESM room when the submarine went to periscope depth. The ESM station had one set of headphones. When the ESM antenna broke the water's surface, at 1338, the under-instruction ESM operator listened on the headset for aural indications of nearby vessels, and the qualified operator listened to the open microphone for the OOD-2's report.[27]

The qualified ESM operator said that he asked the under-instruction ESM operator what he thought, and that he responded there were multiple contacts but none was close. He said that before the OOD-2 announced, "No close contacts," he took the headset and listened to the aural indications. The categories of signal strength range from 1 to 5, with 5 being the strongest. The qualified ESM said that he heard none with a signal strength of 4 or 5, which would indicate a close-in contact. Upon hearing the OOD-2's announcement, the qualified ESM operator told the unqualified operator to announce, "No close contacts."

Emergency Evolutions. The CO testified that because there were "no visual contacts" and because both sonar and ESM had reported no threat contacts, "I called [an] emergency deep as a training evolution. . . . It was obvious that it took the control room party by surprise, which, for a training evolution of this type, I intended to do."

By the time that the CO ordered the emergency deep dive, about 1340, the FTOW had entered three solutions for S-13 using a range value of 3,000 yards. The fire control system display continued to indicate that his solution was accurate. Reconstructed system data show that, at 1339:50, the *Ehime Maru* was at a range of 2,236 yards, or 1.10 nautical miles. (See figure 8.) The FTOW later stated that, just before the emergency main ballast tank (EMBT) blow, he adjusted the range in his solution to 9,000 yards based on the fact that the CO had just completed a visual search and not reported seeing any close contacts.[28]

As the submarine descended, the CO asked the quartermaster the course to P/H, and the quartermaster responded that it was 340°. The CO then ordered a course change to 340° to head the submarine toward its return point.

[27] Naval Warfare Publication 3-55.42 stipulates that the ESM's defensive aural search should be conducted in the same time as the OOD's initial search for close contacts, that is, within 24 seconds.

[28] Data indicate that the FTOW changed the range to 9,000 yards after the collision.

The guests stated that the CO then asked them whether they would like to participate in the vessel's upcoming evolution, which was the EMBT blow. During this maneuver, high-pressure air is used to force water out of ballast tanks as rapidly as possible to bring the submarine back to the surface in the shortest possible time. For the maneuver, the CO personally assigned one guest to sit in the helmsman's chair and operate the helm controls and stationed another guest to operate the valve levers that released the high-pressure air into the main ballast tanks. A third guest was stationed at the diving alarm. Experienced crewmembers supervised the visitors at the controls throughout the evolution, and the CO narrated what was happening for the visitors' information during the submarine's ascent. The FTOW said that during the EMBT blow, the civilians who were standing were "holding on to stuff—whatever they could grab onto to help stay up."

The sounding of the alarm was the signal to begin the emergency blow maneuver. At this time, witnesses reported, the guest at the high-pressure air controls operated the levers under close supervision of Navy personnel, and the submarine started to rise at a sharp angle. The guests recalled that, shortly afterward, there was a loud noise, and the submarine shuddered. The guests quoted the CO as saying, "What the hell was that?" After the submarine slowed and the periscope could be raised, the CO looked into the periscope and announced that the submarine had struck another ship. (See figure 10.)

Figure 10. The collision between the *Greeneville* and the *Ehime Maru* occurred about 9 miles south of Oahu, Hawaii, at position 21°05.5' N, 157°49.1' W. Dotted line indicates the edge of the submarine's assigned submerged operating area.

The FTOW said that immediately after the collision, he went into sonar and talked with the sonar crew to determine whether they still had the contacts they had been tracking. He said that he was surprised to learn later that the vessel struck by the *Greeneville* was indeed one of the contacts they had been tracking. He said that he assumed that the ship they hit had been "dead in the water," meaning its machinery was turned off.

Sinking of the Ehime Maru

Personnel on board the *Ehime Maru* reportedly heard two loud noises and felt the fishing vessel shudder. The bridge crew all stated that they did not see anything before the collision. According to the *Ehime Maru*'s master, "There was no ship at all nearby." He stated that "the range of vision was good" and that "there was no outline of a ship nearby on the radar," a Tokimec model BR-3440MA-X59. He said that he then felt two impacts and the stern of the ship lifted up.

After the impact on the fishing vessel's port aft quarter, the *Ehime Maru* bridge personnel looked aft and saw the submarine as it broached the surface of the water. The *Ehime Maru*'s lookout said that after observing the submarine, he turned forward and saw diesel fuel squirting from the fuel tank vent on the forward port side of the fishing deck. The *Ehime Maru*'s master said that he realized immediately that his vessel was in trouble. Within 5 seconds of the collision, the *Ehime Maru* lost all power, including the backup systems on the emergency generator circuit. He said that he tried to call for assistance using the VHF-FM marine band radios, but they would not work. The master directed the chief radio operator to activate the emergency position indicating radio beacon (EPIRB), a portable 406-MHz model with a hydrostatic release, that was installed immediately outside the pilothouse, on the port bridge wing. (See figure 11.) According to witnesses, the chief radio officer was wearing an automatically inflating lifejacket and was near the bridge when the vessel began to sink. No one recalled seeing him reentering the pilothouse, leaving the ship, or swimming in the water.

Meanwhile, on the third deck (the lowest deck of the fishing vessel), the chief engineer, the first engineer, and the first oiler were in the engine control room when the oiler said he heard a loud scrape and then felt an impact. He said that the space immediately went black, and water and fuel flooded the area with such force that he was "violently" knocked about. He said that he could not recall how he was able to escape the engineroom but thought that water gushing in had carried him through the engineroom and up through a deck opening to the second deck. From there, he climbed up the ladder and out of the vessel. He said that he never saw the chief engineer and the first engineer after the impact.

At the same time, on the second deck, the nine students who survived the accident had just finished lunch and were either in the crew mess or in cabins that were immediately forward of the mess. The four students in the crew mess went directly aft. The students in their cabins said that when they looked out into the passageway, they saw

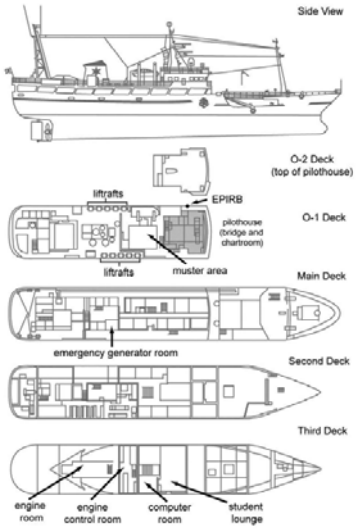

Figure 11. Side view of the *Ehime Maru* and plan views of the decks.

water and oil gushing up the stairwell from the deck below. The *Ehime Maru* was equipped in the berthing areas and at the watch stations with automatically inflating lifejackets that met the standards of the International Convention for the Safety of Life at Sea, 1974 (SOLAS), as amended. Most of the surviving students were able to retrieve the lifejackets from their cabins; other students said that they did not think to do so. They said that as they went aft in the passageway, they had to wade through an ankle-deep mixture of oil and water. Most of the students first went to the funtail area, or stern overhang, of the main deck. From there, they went to the mustering station aft of the pilothouse.

All survivors reported gathering in the muster area behind the pilothouse. Several witnesses stated that after it settled in the water, the *Ehime Maru* then sank by the stern at a 30° to 45° angle within 5 minutes of the collision. As the ship began to submerge, some people went into the water or were washed off by the waves coming over the stern. The remaining personnel attempted to climb a ladder to get onto the top of the pilothouse. Two students were washed off the ladder into the sea. Other students and crewmembers reached the top of the pilothouse only to be washed off by waves as the vessel sank. The oiler stated that he injured his shoulder when a wave washed him against a searchlight mounted on top of the pilothouse. Survivors carried underwater with the sinking ship either swam up to the surface or their lifejackets automatically inflated and carried them up. Witnesses from the submarine and the *Ehime Maru* reported that, after the fishing vessel sank, the water was covered with a heavy sheen of oil.

The *Ehime Maru* also carried 10 SOLAS-approved liferafts in containers mounted with hydrostatic releases that were designed to activate when the vessel sank to water depths ranging from 5 to 25 feet. The raft containers would then float to the surface and be automatically inflated by "tag lines" attached to the vessel with breakaway links.

According to personnel who escaped the vessel and made it to the water's surface, the liferafts functioned as designed, and survivors were able to climb into them. The second engineer wound up in a raft by himself. He said that the submarine approached him and its crewmen called out to him. He yelled back, but the English/Japanese language barrier prevented him from understanding them.

Emergency Response

After determining that the *Greeneville* had struck a surface vessel, the submarine CO reported the collision to the Navy's COMSUBPAC operations center at 1348. COMSUBPAC center personnel, in turn, notified Navy command personnel and Coast Guard Group–Honolulu by both landline telephone and VHF-FM marine radio. The Coast Guard and then the Navy began sending search-and-rescue assets to the scene. For a chronology of response events between the collision and the recovery of the *Ehime Maru*'s survivors, see appendix C. An in-depth discussion of response activities follows.

Response Efforts by the *Greeneville*. After the submarine struck the *Ehime Maru*, the *Greeneville*'s engineering officer took over as OOD during the response effort and initiated rescue and assistance measures as required by Operations Procedure (OP)

61-19.[29] In addition, a medical treatment station, manned by a hospital corps technician, was established in the officer's wardroom.

The OOD stated that he and a petty officer manned the bridge, which was located inside the submarine's sail, within 6 minutes of surfacing. The fishing vessel had already sunk, so the OOD conned the submarine toward the *Ehime Maru*'s rafts and debris while the petty officer looked for survivors in the water. Control room personnel searched the area using both periscopes. Because of rough seas, the main deck hatches could not be opened; the only outside access was through the sail access trunk.[30]

The OOD and the lookout were joined on the bridge by the CO and two divers. In preparation for retrieving the fishing boat's occupants, the divers, who were trained in basic first aid, rigged a Jacob's ladder, which is a rope ladder with wooden or plastic steps, down the side of the sail.

As the submarine neared two rafts of survivors, the OOD called out to and tried to communicate with the people; he said that he was not successful, however, because of the English/Japanese language barrier. He saw one person who appeared to be injured lying in a raft. He said that because he had been advised that Coast Guard resources were soon due on scene, he elected not to put a diver in the water. He further stated, however, that if the submarine crew had seen any people from the *Ehime Maru* in the water before the Coast Guard boats arrived, he would have had a diver go to their aid.

Actions by COMSUBPAC. When COMSUBPAC received initial notification at 1348, its command personnel assumed search-and-rescue mission coordination for the Navy response and identified immediately available Navy resources to dispatch to the accident site. At 1355, COMSUBPAC watchstanders notified Coast Guard Group–Honolulu of the accident. Navy officials said that, during the initial phase of the response, they dispatched Navy vessels and aircraft independent of the Coast Guard response. However, COMSUBPAC maintained an open telephone line to Coast Guard Group–Honolulu to keep apprised of developments.

According to Navy officials, at 1504, based on information received about the scope of the accident, COMSUBPAC transferred search-and-rescue mission control of the dispatched Navy assets to the Coast Guard. (See next section.) The COMSUBPAC operations center continued to independently identify and launch Navy air and sea resources, notifying the Coast Guard when the response assets were en route.

[29] The Naval Sea Systems Command has published the rescue and assistance procedures contained in the Los Angeles Class ship systems operations manual as a separate classified reference document, OP 61-19. The OP includes the actions to take and which crewmember is responsible for taking them should certain types of emergencies occur. The reference document also lists the precautions and the safety limitations that the rescue and the assistance details must follow when responding to an emergency.

[30] Videotape taken by the Coast Guard response helicopter shows large waves washing across the *Greeneville*'s main deck.

January 2014 303

Coast Guard Response. According to the duty officer at Coast Guard Group–Honolulu communications center, when he received notification at 1355 of a collision in the area south of Diamond Head, he assumed responsibility as search-and-rescue mission coordinator for the case, in accordance with the agency's standard operating procedures. He first ordered a Coast Guard HH-65A helicopter (No. 6570) on routine air patrol to divert to the accident site and then ordered Coast Guard Station–Honolulu to send rescue boats to the scene.

Coast Guard Station–Honolulu initially dispatched two vessels: a 21-foot rigid hull inflatable boat (RHIB) with 3 crewmembers and a 41-foot patrol boat with 7 crewmembers, including an emergency medical technician. The Group duty officer said that when he realized that the Coast Guard's standby cutter, the *Kittiwake*, was several hours away from the accident site, he ordered the recall of the Coast Guard cutter *Assateague*, which was at home base in a maintenance status. The *Assateague*, staffed with off-duty personnel from several cutters, got under way within 1 hour of notification.

Helicopter No. 6570, with two pilots, a hoist operator, and a rescue swimmer on board, arrived at the site at 1427, about 45 minutes after the collision, and assumed command of the on-scene response. The helicopter pilot centered on the rafts and debris and, at 1446, began a sector search for people in the water.

In the meantime, the RHIB and the patrol boat arrived at the scene at 1431 and 1444, respectively. The RHIB went from raft to raft, counting people, identifying who had sustained injuries, and searching for someone from the *Ehime Maru* who spoke English. According to the coxswain on the RHIB, the master of the *Ehime Maru* was located in a raft and taken on board. The fishing boat master and the RHIB crew continued to count survivors in the rafts and determined that 9 people were missing. The Coast Guard responders radioed a report about the missing personnel to Group Honolulu.

When the Coast Guard patrol boat arrived on scene at 1444, the helicopter lowered its rescue swimmer by hoist to the boat, which then maneuvered next to three liferafts that were tied together. The rescue swimmer moved from raft to raft, assessing the condition of the survivors and treating those who were injured. He immobilized the arm and shoulder of the injured oiler and, using bottled water from the raft survival kits, flushed the eyes of those who had eye irritations from the diesel fuel.

The RHIB retrieved and ferried survivors from the other rafts to the patrol boat, where the EMT-trained crewmember medically assessed their conditions. The on-scene responders then distributed the 26 survivors between the two Coast Guard boats and returned to Coast Guard Station–Honolulu, arriving there about 1615.

Joint Rescue Coordination Center Response. At 1505, the Joint Rescue Coordination Center[31] assumed the responsibility of search-and-rescue mission

[31] The national search-and-rescue plan designates the Coast Guard as the U.S. aeronautical and maritime search-and-rescue coordinator with overall responsibility for the Honolulu region. The agency's

coordinator from Coast Guard Group–Honolulu because of the building magnitude of the case. During the early response, the Joint Rescue Coordination Center did not control or coordinate the influx of Navy resources into the search; however, once the Joint Rescue Coordination Center was advised of the responding Navy resources, center personnel directed the Navy assets to specific search areas and assigned the search patterns.

About the time that the patrol boat and the RHIB were retrieving the *Ehime Maru* survivors, the Coast Guard diverted a C-130 aircraft to the site to relieve helicopter No. 6570 of the on-scene command for the surface and air assets. The Coast Guard cutter *Assateague* subsequently assumed on-scene command of the search and rescue.

Honolulu Emergency Medical Services. The Honolulu emergency medical services dispatcher, working through the communications networks of local hospitals, determined the space availability at the medical facilities and routed ambulances from the Coast Guard Station. The four most seriously injured individuals were taken to Straub Hospital, which treated three of the injured for nausea and eye and throat irritations stemming from diesel fuel ingestion or hypothermia. The oiler was diagnosed with a fractured right clavicle and hospitalized for 5 days.

Because of a lack of available space at Straub Hospital, the remaining five *Ehime Maru* occupants requiring medical attention were taken to Kaiser Permanente Medical Center, where they were treated for eye irritations caused by the diesel fuel and released.

None of the missing personnel was seen after the *Ehime Maru* sank, either by the survivors, *Greeneville* crewmen, or other rescue personnel.

Extended Search Activities

Coast Guard or Navy units were on scene continuously for 22 days, searching for missing personnel. Two civilian vessels of Japanese registry also participated in the search. Initial attempts to locate the fishing vessel were unsuccessful because of bad weather and because of an erroneous report of the accident site. The Safety Board assisted the Navy in determining the location of the *Ehime Maru* by acquiring radar data from the U.S. Air Force 84th Radar Evaluation Squadron and the Federal Aviation Administration (FAA) and filtering the data to plot a track of the *Ehime Maru* that correlated with the time, heading, and speed reported by the master of the fishing vessel. (See discussion in "Safety Board Performance Study" section.) The Navy then moved the search area to the end of the radar track.

On February 16, Navy sonar detected a vessel and, at 1129, Navy personnel were able to identify the fishing vessel by maneuvering a remotely operated vehicle, the *Scorpio II*, so that its video cameras displayed the *Ehime Maru*'s stern plate. The vessel was sitting almost upright in 2,003 feet of water about 1,000 yards from the reported

Joint Rescue Coordination Center, based in Honolulu, is operated by the Fourteenth Coast Guard District and is jointly staffed by Coast Guard and Air Force personnel.

collision site but almost directly under the end of the radar track. For the next week, two underwater remotely operated vehicles, the *Scorpio II* and the *Deep Drone*, searched the *Ehime Maru*'s exterior and the sea bottom surrounding it for the nine missing persons, with no success. The search effort was suspended on March 2.

Salvage Operations

To retrieve the bodies of the *Ehime Maru*'s missing occupants, the Navy contracted to build a specially designed lifting and spreader assembly, which could be operated from a diving support vessel with heavy lift capability. On October 12, 2001, the *Rockwater 2* lifted the *Ehime Maru* about 100 feet above the ocean floor and transported the suspended fishing vessel to a shallow-water recovery site about 115 feet deep near the Honolulu International Airport's reef runway. A team of Navy and Japanese divers then recovered the victims' bodies, personal effects, and mementos, and videotaped the vessel damage. After the search was complete, the *Ehime Maru* was transferred 16.5 miles out to sea, where it was lowered into its final resting place.

At the request of the families of the victims, their bodies were not autopsied and were returned to Japan. The body of the ninth accident victim could not be located, and he is presumed dead.

Damage Surveys

Ehime Maru. An underwater survey of the vessel's bottom revealed a cut in the hull that began on the starboard side inboard of the bottom near the deckhouse front. (See figure 12.) The cut, between 2 to 3 feet wide, ended on the port side shell in the vessel's engineroom, where it extended vertically from the vessel's bottom to 11.5 feet (3.5 meters) above it (the design waterline mark).

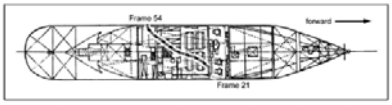

Figure 12. According to diver reports, the line of cut in the *Ehime Maru* extended from frame 21 to frame 54 through both the bottom and the innerbottom of the doublebottom vessel. The cut, therefore, resulted in breaches in the student lounge, the access stairwell to the student lounge, the engine control room, and the engineroom.

The cut proceeded from forward to aft of the vessel and breached the vessel's innerbottom[32] in the student mess, the stairwell, and the engine control room. The cut then proceeded through the bulkhead between the control room and the engineroom, leaving a vertical cutout in the bulkhead that was the approximate shape and size of the *Greenville*'s upper rudder. The vertical outline of the rudder was also visible on the port side shell of the *Ehime Maru*'s engineroom, through which the submarine's upper rudder had exited the fishing vessel's hull. The line of cut had breached several doublebottom (DB) tanks; going forward to aft these tanks included No. 2 fuel oil DB tank (starboard), No. 3 fuel oil DB tanks (starboard and center), and No. 4 fuel oil DB tank (port) in the engineroom. Both the outer and innerbottoms had been cut through. Damage to the control room and to the interior of the student mess and vertical stairtower on the port side of the computer room was visible during the survey. The open vertical stairtower allowed water to immediately flood upward to the upper deck levels of the vessel.

Greeneville. Safety Board investigators conducted a damage survey of the *Greenville* in drydock at Pearl Harbor Naval Shipyard. Investigators found that the sail of the submarine showed no damage. Immediately below the sail, the acoustic hull surface treatment (tiles) on the portside hull had been sheared off in an elliptical pattern about 24 feet long.

The upper rudder, located at the submarine's stern, showed the greatest impact damage. The damage began at the 31-foot draft mark and extended all the way to the top of the upper rudder on both its port and starboard sides. Surface tiles had been sheared off exposing bare metal over most of the rudder surface, and there were several indentations on the rudder's leading edge. One of the larger indentations had punctured the metal skin on the port side. The anchor light had been sheared off the top of the rudder. Other scrapes and missing paint seen on the hull were correlated by the Navy to previously existing wear and tear on the ship. The propeller area had not been damaged.

Safety Board Performance Study

As noted earlier, the Safety Board assisted the Navy in locating the sunken fishing vessel by obtaining Air Force and FAA radar data and extracting the *Ehime Maru*'s trackline. Safety Board engineers also used the radar data as well as own-ship, sonar, and fire control data retrieved from the *Greeneville*'s sonar data logger (SLOGGER) to conduct a performance study of the *Greeneville*, the *Ehime Maru*, and other surface vessels around the time of the accident. Excerpts from that study are summarized below. Note that the study and all the plots exclude the classified speeds and depths exceeded by the submarine during the visitor cruise.

The complete performance study is part of the public docket maintained on this accident by the Safety Board at its headquarters in Washington, D.C. For additional

[32] The *Ehime Maru* had a doublebottom design, meaning the bottom of the ship had a compartment used for fuel, ballast, and so forth that was topped by a shell plating. This plating is referred to as the innerbottom.

details on the development of the tracks of the *Ehime Maru* and the *Greeneville* and the plots comparing all nonclassified recorded data and fire control solutions, see the public docket.

Ehime Maru *Track*

To determine the position of the *Ehime Maru*, Safety Board engineers sorted the radar data obtained from the Air Force and the FAA and removed any radar return that was not south of the radar site or that originated from aircraft with transponders. The remaining radar returns were plotted as a function of time to identify radar tracks, that is, consecutive radar returns. The radar data having the characteristics of surface ships (slow speed, no aircraft transponder return) were obtained from Honolulu airport, which uses Airport Surveillance Radar Model 9 (ASR-9). The airport radar antenna has an elevation of 68.1 feet and a magnetic variation of 10.5° E. The Safety Board converted azimuth and range data to east and north position from this antenna using the Tracks software program. One track visible in one of the plots ended at 2343 Universal Coordinated Time (UTC), or 1343 local time. This was later established as the time of the collision, initially from witness interviews and then from system data.

The radar tracks in the plots were separated and compared with sonar data. One track ended at the wreckage site and at the 2343 UTC collision time (as seen in own-ship data). This radar track was considered to be the *Ehime Maru*. The track showed the *Ehime Maru* moving at 11 knots on a heading of 166°.

Greeneville *Track*

The digital audio tape (DAT) information captured from the sonar interface unit consisted of TARed (a UNIX compression standard) ASCII data, which Safety Board engineers uncompressed on a UNIX workstation, transferred to a computer, and recorded onto a CD-ROM. The files consisted of data for the *Greeneville*'s motion (own-ship data), towed-array parameters,[33] and sonar and fire control data parameters. The recorded own-ship parameters consisted of time, heading, pitch, roll, depth, and speed. Angular data were obtained from the inertial navigation system. All own-ship data were recorded once a second; however, some data points were missing and the recording time sequence was occasionally offset briefly. Because the speed and direction of a submarine cannot change much in 1 second, Safety Board engineers manually repaired the bad data points. From the own-ship data, the Safety Board developed the plots shown below. Figure 13 shows the *Greeneville*'s keel depth and heading for the period between the ascent to periscope depth and the collision.[34]

[33] Because the towed array was not deployed, the towed-array parameters were columns of zeros.

[34] The keel depth data held 90.84 feet for 7 seconds immediately before the collision. The Safety Board worked with the Navy to determine the cause of this false reading, but nothing conclusive was determined.

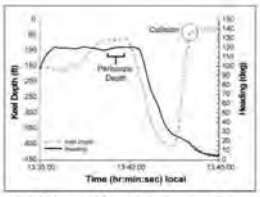

Figure 13. Keel depth and heading of the *Greeneville* between the ascent to periscope depth and the collision.

Integrated Tracks

The integrated plot of the *Greeneville* track and the *Ehime Maru* track developed by Safety Board engineers appears in figure 8. The Safety Board also developed a three-dimensional representation of the *Greeneville* and *Ehime Maru* tracks, beginning with the submarine's ascent to periscope depth and ending at the wreckage site. (See figure 14.)

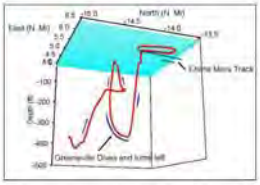

Figure 14. Three-dimensional representation of the *Greeneville* and *Ehime Maru* tracks, showing the submarine's ascent to periscope depth, the diving left turn, the collision with the *Ehime Maru*, and the return to the wreckage site. Note that depth is not to scale with east and north position.

Postaccident Actions by the Navy

Navy Court of Inquiry

General Findings. On February 9, 2001, the COMSUBPAC ordered an official inquiry into the collision between the *Greeneville* and the *Ehime Maru*. In its final report, the court of inquiry issued 26 recommendations, which, among other actions, included disciplinary measures against shore-based officials and six *Greeneville* crewmembers and reviews of various programs and procedures for adequacy and compliance.

Disciplinary Actions. Based on the findings and recommendations of the court of inquiry, the *Greeneville*'s CO was taken to Admiral's Mast,[35] where he was found guilty of committing two violations of the Uniform Code of Military Justice: dereliction of duty and negligent hazarding of a vessel. He was "detached for cause" from his position as CO, which was documented in his Navy officer record. He submitted a request to retire, which was approved, and he retired effective October 1, 2001.

The OOD-2 was taken to Admiral's Mast, where he was counseled for failing to execute his duties to ensure the safe navigation of the ship and to properly supervise watch personnel in the control room. The FTOW was taken to Captain's Mast for failing to report a closing sonar contact (the *Ehime Maru*) in accordance with standing orders.

The XO and the chief of the boat were both admonished for lack of oversight and execution of the enlisted watchbill.[36] The sonar supervisor was admonished for his poor watchstanding and backup of the contact management team and his failure to ensure that only qualified personnel stood watch in sonar.

The FTOW and the sonar supervisor were required to requalify before standing another underway watch in their supervisory positions.

Program Reviews. The court of inquiry report stated that various programs and operating procedures should be reviewed for adequacy and compliance. Table 2 summarizes the tasks the court recommended that COMSUBPAC or the Navy should accomplish.

[35] Mast is an administrative proceeding where a senior officer can impose nonjudicial punishment for disciplinary offenses that do not merit courts-martial.

[36] Some individuals listed on the watchbill were not on the vessel and, no one was initially assigned to the fathometer watch, which is a station that must be manned when operating within 10 miles of land. The sonar supervisors switched personnel to accommodate for the oversight. The Navy found that, on the day of the accident, 9 of the 13 watch stations during the second underway were not stood by the individuals assigned to them. Several crewmen switched watches with a fellow crewmember without advising their supervisors or obtaining their permission to change duty assignments.

Table 2. Court of inquiry recommendations and actions taken

Task	Actions Taken
Ensure compliance with operating standards that permit only fully qualified sonar technicians to stand sonar watch.	In June 2001, COMSUBPAC issued guidance by classified message to subordinate echelons and all Pacific Fleet submarines reemphasizing sonar watchstanding requirements. The message directed that under-instruction sonar watchstanders be supervised by a qualified watchstander assigned on the watchbill to that station, not by the sonar supervisor. Compliance with sonar watchstanding qualifications and sonar watchstanding proficiency is now routinely inspected during the interdeployment training cycle.
Review the adequacy of the COMSUBPAC Operational Risk Management (ORM) program.	COMSUBPAC conducted an internal audit of COMSUBPAC to ensure compliance with Navy ORM instructions in OPNAVINST (Chief of Naval Operations Instruction) 3500.39. In June 2000, Commander of Naval Forces instruction 5040.12 was revised to require that ORM be used in interdeployment training cycle inspections and assessments.
Review the ability and means of submarine squadron commanders and their staffs to provide meaningful oversight and objective feedback to their submarine commanding officers and crews during the interdeployment training cycle.	On August 28, 2002, a classified COMSUBPAC instruction was revised to include comprehensive interdeployment training cycle management. A squadron commander now conducts a 2-week assessment early in each submarine's interdeployment training cycle to identify, among other things, the strengths and weaknesses in basic submarine operations. The assessment results are used to focus training during the interdeployment training cycle to prepare the submarine crew for its next overseas deployment.
Coordinate a review of submarine open-ocean search-and-rescue capabilities and requirements with the lead type commander and make appropriate recommendations to the Chief of Naval Operations.	Naval Warfare Publication 3-50.1 (rev. A) promulgates Navy doctrine for search-and-rescue operations. The publication is subject to periodic review and update. It has been updated by change on three occasions since February 9, 2001. No changes were suggested by the Navy's court of inquiry report and none of the intervening changes relate specifically to submarine open ocean search-and-rescue operations.
Review the maritime traffic density of the Hawaiian operating area with the Coast Guard and other appropriate government agencies every 3 years.	A COMSUBPAC memorandum, dated April 23, 2001, now requires a maritime traffic density review for submarine force training agendas.
Provide information and training to the force concerning the *Greeneville* collision.	On April 23, 2001, COMSUBPAC sent a "lessons learned" message to all COMSUBPAC COs. The message was followed by a classified joint message from the commanders of the U.S. Atlantic and Pacific submarine forces, summarizing the main findings and conclusions of the investigation as approved by the Commander of the Pacific Fleet. All submarine wardrooms and senior enlisted quarters have conducted training on the factors that contributed to the collision. A case study of the collision between the *Greeneville* and the *Ehime Maru* has become part of the curriculum at each level of tactical training for submarine officers. In addition, each wardroom is required to train on this case study annually.

The court of inquiry report concluded that the Navy's distinguished visitor program should be fully supported. However, the court recommended that the COMSUBPAC coordinate with the Chief of Naval Operations and the Naval Chief of Information to conduct a complete review of Navy public affairs policy and guidance on

the embarkation of civilian visitors, and to issue new guidance that was internally consistent, clear, and more specific. The report also recommended that the approval authority for distinguished visitor embarkations be delegated to commanders at the type level, which is the second echelon to the fleet command. In the case of the Pacific submarine fleet, the type commander was the COMSUBPAC.

Regarding the conduct of distinguished visitor cruises, the court of inquiry recommended that COMSUBPAC identify which evolutions were appropriate for demonstration and reemphasize to the force that classified operational depths and speed limits are inappropriate for civilian cruises. The court of inquiry further recommended that COMSUBPAC establish a formal means for disseminating feedback or sharing information regarding distinguished visitor experiences across the command.

Revision of Instructions Addressing Visitor Cruises

At the Navy's court of inquiry, the COMSUBPAC testified that the Navy had both Secretary of the Navy instructions (SECNAVINST) and OPNAVINST addressing distinguished visitor cruises, a "tiny" but "extremely important" part of the Navy's civilian outreach program.[37] COMSUBPAC had issued operations orders and instructions pertaining to visitors on ships; however, the COMSUBPAC guidance documents basically iterated the policies put forth in the instructions issued by the Chief of Naval Operations and the Secretary of the Navy.

Neither of the publications cited by service officials contained requirements for ensuring the safety of civilians embarked on Navy vessels.[38] The instructions also did not address the procedural issues of whether and when civilians should be permitted in the control room or the sonar room and, if so, how many visitors should be allowed. The guidance did not indicate whether or when interaction between visitors and watchstanders should be allowed or define the role of the CO during a visitor cruise. In addition, the instructions did not specify which maneuvers should be conducted for the benefit of the distinguished visitors or, more importantly, prohibit any deviation from standing orders that might jeopardize the submarine, its crew and passengers, or vessels in the vicinity of the submarine's operating area.

Following the *Greeneville* collision with the *Ehime Maru*, chapter 4 of SECNAVINST 5720.44A was revised in May 2002, transferring the oversight for

[37] In calendar year 2000, the entire Pacific fleet sponsored 176 guest embarkations, providing cruises for about 8,000 civilians. Of the 176 cruises, COMSUBPAC had 51 embarkations for 1,354 guests. Of the COMSUBPAC guest embarkations, 12 cruises carrying a total of 213 civilian visitors originated from Pearl Harbor. The COMSUBPAC stated that this total was less than the total embarkations in 1999, when SUBPAC hosted 227 civilians on 18 visitor cruises that originated from Pearl Harbor.

[38] In addition, none of the 26 Department of Defense, Navy, and Marine Corps documents cited as references for SECNAVINST 5720.44A addressed safety measures for civilian visitors on Navy ships, nor did they include procedural differences in submarine operations that were unique to visitor cruises.

distinguished visitor embarkations to commanders at fleet level, which for Naval forces in the accident area was the Commander, U.S. Pacific Fleet.

In August 2003, COMSUBPAC issued COMSUBPACINST 5720.1, which contained procedures for handling public visits on Pacific Fleet submarines that supplemented SECNAVINST 5720.44A, Commander of Naval Submarine Forces (COMNAVSUBFOR) OPORD 2000 (appendix 4), and SECNAVINST 5510.34. COMSUBPACINST 5720.1 procedures stipulate rules and requirements for each distinguished visitor embarkation on a Pacific Fleet submarine. The section pertaining to civilian distinguished visitor cruises states, "Civilian embarkations pose a degree of risk that must be properly managed."

The revised COMSUBPAC instructions address omissions in previous guidance documents, for example, interaction between watchstanders and visitors, the conduct or prohibition of certain maneuvers, and whether and how many civilian visitors should be permitted in the control room during certain evolutions. The instructions specify, in part, the following:

- Visitors should receive an introductory safety brief that advises them of what to expect in an emergency and how to don protective gear.
- Embarkations are to remain unclassified. The ship will not exceed unclassified depth or speed.
- The CO "will ensure guests do not inhibit the safe operation of the ship."
- One crewman will be assigned as a dedicated tour escort for every four to eight guests, and the watchbill will include those crewmembers serving as tour escorts. The escorts will have no other assigned responsibilities during the underway.
- The crewmembers assigned as tour escorts should be selected "to ensure first the safety of the visitors, then satisfy their information needs."

The procedural changes now require that requests for cruises be submitted in writing through the submarine's chain of command either to the COMSUBPAC or, if the hosting submarine is deployed, to the fleet commander. The requests must include a schedule of key events, and the force commander must review the planned maneuvers in terms of appropriateness for the assigned operating area, taking into consideration the shipping and fishing vessel density, water depth, and any other hazards to safe conduct. The August 2003 instructions prohibit allowing civilian visitors to operate any equipment; however, as part of the event schedule submission, the CO may propose allowing civilians to operate certain equipment during specific events while under the direct supervision of a qualified watchstander. Such a proposal must be approved by the force commander.

COMSUBPACINST 5720.1 permits up to 24 visitors, including noncrew escorts, on a civilian embarkation. The criterion for selecting an escort who accompanies the

guest groups is "to ensure first the safety of visitors, then satisfy their information needs." The CO or his agent must review the itinerary developed for the visitors for areas of "conflict," that is, where overcrowding might occur.

In addition to the required procedures, COMSUBPACINST 5720.1 contains recommended actions for ensuring the safety of ship operations. For example, the initial briefing to visitors should be conducted in the mess facility during the outbound transit so that the piloting party can function without distraction. To ensure that the control room is not overcrowded during evolutions, the plan of the day should include two surface and dive evolutions, the implication being that a guest group of 24 should be divided and fewer visitors allowed in the control room at one time. To ensure that the crew is not distracted while making preparations to go to periscope depth, the visitors should be taken to the mess facilities, where they can watch a movie or a monitor linked to the PERIVIS.

Oversight Changes

During his interview with Safety Board investigators, the COMSUBPAC Deputy Chief of Staff for tactics and training described several "subtle" changes affecting squadron oversight of the *Greeneville* that were not recognized as having a combined detrimental impact until the Navy investigated the collision.

The COMSUBPAC deputy pointed out that a ship typically comes back from one deployment and deploys again within about 15 months. Because the *Greeneville* was a test platform for the Advanced SEAL Delivery System, it was not in the squadron's regular deployment rotation. As a result, Squadron 1 conducted fewer observations of the *Greeneville* and made fewer formal reports on its operations than in the past.

Beginning in 1999, the Navy changed the required oversight practices for the squadrons. Instead of stipulating that, at a minimum, the squadron conduct a tactical examination on a ship every 12 to 15 months, the Navy keyed the tactical examination to the vessel's interdeployment training cycle. As a result of the *Greeneville*'s extended interdeployment training cycle, the squadron had not conducted a formal tactical examination since 1998, when the submarine was fitted with the Advanced SEAL Delivery System.

About the same time that the Navy changed the squadron oversight standards, it also reorganized the squadron commands, which resulted in staff reductions. According to the COMSUBPAC deputy, during the transition period from the old to the new squadron command organization, the oversight infrastructure of the commands was "probably not well focused."

The COMSUBPAC deputy said that while the squadrons were being reorganized and oversight practices were being changed, the newly appointed commander to Squadron 1 "was struggling with another boat that had a . . . series of problems" but that was on a deployment cycle and had to be ready to go to sea by the end of December 2000. He said that when the Squadron 1 commander and other senior personnel visited

the *Greeneville*, the "superficial" indicators of readiness all looked good. The boat was clean. The crewmembers were "positive . . . happy with their leadership . . . and proud of their organization." Moreover, crew retention was good.

The COMSUBPAC deputy said, "If we had taken the time . . . and studied in detail . . . the fundamental practices on the ship, I think that we would have seen the harbingers of problems." He stated that since the *Greeneville* collision, the Navy has changed the method for evaluating submarines. All boats are evaluated regularly, regardless of their deployment cycles. The focus is on forcewide performance in a particular area. The evaluation is a multistep process:

- *Basic submarine assessment.* Evaluate the submarine crewmembers to determine their fundamental understanding of their jobs and responsibilities.
- *Corrective actions.* Identify and monitor actions to correct problem areas; evaluate the weak areas the next time the vessel goes to sea.
- *Second formal review.* Two inspections are conducted 6 to 8 or 9 months after the basic assessment to check the ship's readiness to deploy. The first inspection is conducted by the squadron commander, the second by the COMSUBPAC staff and training office. The inspection team "baselines them against everyone else." The squadron commander then directs the CO to correct identified problems.

At a minimum, a ship must receive a passing grade on three major tactical events in a 15-month period. In addition, the submarine must pass two engineering inspections. Squadron personnel are on board and watching and tracking the ship's procedures during all events. Every ship is graded to an absolute common standard by the use of grade sheets. The squadron deputy told Safety Board investigators, "I think there's a great deal of sensitivity . . . to readiness, almost to the point that we've overcorrected in a way." He said that, in late 2001 and early 2002, two or three ships had not left on time because of unreadiness detected in the inspection process.

Operational Risk Management Program Changes

The Navy's court of inquiry found that, "Had *Greeneville*'s CO and crew been practicing the basic tenants of ORM, the collision may have been avoided." The court of inquiry recommended that COMSUBPAC review the adequacy of its current ORM program.[39] The stated purpose of the Navy's ORM program is to minimize risks to acceptable levels, proportional to mission accomplishment. The Navy's ORM is a closed-

[39] Finding 66 and recommendation 8 of the court of inquiry report (Record of Proceedings, *Court of Inquiry into the Circumstances Surrounding the Collision Between USS Greeneville [SSN 772] and Japanese MV Ehime Maru That Occurred Off the Coast of Oahu, Hawaii, on 9 February 2001*, U.S. Navy, April 13, 2001).

loop process that supervisory personnel use to identify and control hazards. The process involves the following five steps:

- Identify hazards;
- Assess hazards;
- Make risk decisions;
- Implement controls; and
- Supervise.

The level of an ORM analysis is time-critical, deliberate, or in-depth, depending on the situation. The depth and formality with which a supervisor conducts an ORM is guided by the following four principles:

- Accept risk when the benefit is greater than risk;
- Accept no unnecessary risk;
- Anticipate and manage risks by planning; and
- Make risk decisions based on the right level of analysis.[40]

As noted in table 2, following the adjournment of the court of inquiry, COMSUBPAC conducted an internal audit of its operations to ensure compliance with Navy ORM instructions. In addition, Navy instructions were subsequently revised in 2003 to include assessments of the use of ORM in training inspections.

Course and Training Changes

After the *Greeneville*'s collision with the *Ehime Maru*, the Navy revised its basic submarine course and all officer training, including the content of courses, entrance tests, and final examinations, the conduct of training, and the appropriateness of assignments for skill development. The courses now integrate the lessons learned from the *Greeneville* accident.

[40] OPNAVINST 3500.39A.

Analysis

In its review of the events in this accident, the Safety Board determined that qualified and experienced members of the combat management team (the conning officer, the FTOW, and the sonar supervisor) as well as senior officers who happened to be in the control room failed to follow procedures designed to ensure safety in operations. The teamwork problems demonstrated on the day of the collision were due in part to the CO's overly directive style, particularly with the OOD-2. However, the failure of key watchstanders to effectively perform their duties and communicate vital information to the conning officer contributed to the CO's committing the following critical errors:

- Failed to perform adequate contact analysis;
- Rushed the procedures for moving to periscope depth; and
- Ordered an emergency surfacing maneuver in the direction of a contact.

Contributing to the operating errors of the combat systems team was their failure to adequately manage the civilian visitors so that they did not distract the watchstanders from the efficient execution of their duties. A detailed discussion of the operating errors follows. The analysis also considers the design of the *Ehime Maru* and the survivability of the fishing vessel in the accident.

Failure to Perform Adequate Contact Analysis

To accurately determine the range, course, and speed of a vessel contact, the combat systems team needed to interact to ensure that a sufficient change in the contact's bearing rate was generated. For the visitor cruise, the *Greeneville* had no established track. The submarine sailed almost straight south and then, with the exception of one baffle clear, almost straight north while operating at a keel depth of 600 to 650 feet during much of the submerged underway. According to Navy officials in charge of tactical training, a crew can do "solution development without maneuvering the ship by using a variety of ranging techniques," and "operating at 600 feet reduces or minimizes the need for a precise solution" until the submarine is preparing to go to periscope depth. Navy officials who testified at the court of inquiry or who were interviewed by Safety Board investigators indicated that TMA could have been performed either immediately before or immediately after the *Greeneville* conducted the evolutions, so long as it was conducted before the submarine proceeded to periscope depth. Thus, it was not inappropriate for the combat systems team to wait until later in the underway, shortly before preparing to surface, to concentrate on contact (or target) motion analysis.

Problems arose, however, when both the sonar supervisor and the FTOW made assumptions about the contacts, including S-13 (the *Ehime Maru*), which later resulted in their providing incomplete and erroneous information to the CO. When sonar acquired S-13, the sonar supervisor correctly assessed that the vessel was distant and that it was

not showing much of a bearing rate. However, when the bearing rate remained small for more than 40 minutes, he incorrectly assumed that the vessel was island traffic, on a distant course, and probably moving away from the submarine. He thus failed to properly assess the potential risk, anticipate a dangerous scenario, and advise the CO that the *Greeneville*, steering 000°, and the S-13 (the *Ehime Maru*), bearing 358°, were on closing courses.

The FTOW indicated that sonar did not designate any of the contacts as merchant ships. He stated that "just being in Hawaiian waters," he assumed that the contacts were typical of the "traffic around here . . . probably trawlers, fishing vessels [and] pleasure crafts." He too thought that S-13 was distant and did not enter a tracking solution for the contact for 16 minutes (between 1240 and 1256). As further evidence that he did not consider S-13 a threat contact, at 1257:45, he changed his tracking solution for S-13 to place it on an opening course despite having no analysis showing that the contact was actually opening.

Problems were exacerbated when the CO did not use all his resources to correctly assess the current operating situation when preparing for the conduct of the evolutions in the control room. He elected to confer with his trusted senior petty officers, first visiting sonar, where he was briefed by the supervisor, and then stopping at the fire control station, where he talked with the FTOW. The CO later stated that he had assumed that the OOD-2 had conducted TMA and had been confident that the young conning officer knew where the submarine was in relation to the contacts; yet, he never discussed the contact picture with him. The OOD-2 was aware that the combat systems team "did not have a great contact picture of where [S-12 and S-13] were" before the evolutions began. For his part, the OOD-2 assumed that some evolutions would be cancelled because the submarine was due back at P/H at 1400 and that a senior officer would brief him about the changes. The CO and the OOD-2, as the first- and second-level officers in the operational chain of command, should have conferred, not only about the contacts, but also about the safe completion of the voyage.

The CO testified that he went into sonar to assay the contact picture for himself. He recalled that in his discussion with the sonar supervisor, he was told that sonar held two contacts, a merchant vessel to the northwest [S-12] and a surface craft to the northeast [S-13, the *Ehime Maru*]. The sonar supervisor told the CO that the contacts "were distant, [and] up by land," and more than 10,000 yards away. Thus, the CO assumed that the contacts posed no danger. The sonar supervisor did not advise the CO that S-13 had not shown any bearing drift for 40 minutes, that the course of the *Greeneville* had been on a straight south/north track throughout most of the cruise, or that the submarine and S-13 were on closing courses. Had the sonar supervisor communicated this information, the CO might have recognized the potential risk and not taken the operational shortcuts that he later did.

The CO then entered the control room, where he said he reviewed the fire control monitors and discussed the contact status with the FTOW. The fire control technician made almost the same comments about the contacts being typical Hawaiian marine traffic as the sonar supervisor had done, which reinforced the CO's opinion about the position

and course of the contacts. When he approached the conn, the CO then observed and recalled that the AVSDU was not working. If he had reviewed the CEP, which the FTOW maintained until an hour before the evolutions, the CO might have realized that the movements of the contacts and the submarine had been inadequate for good contact analysis. Instead, he chatted with the visitors, advising them where to stand for the best view of the evolutions, which prompted several civilians to position themselves in front of the CEP, blocking the CO's view of it and the FTOW's access to it.

Rushed Procedures for Movement to Periscope Depth

At the onset of the angles and dangles, rather than properly oversee the OOD-2 by having him direct vessel movements that the CO could verify as being correct, the CO essentially took over the conn without acknowledging that he was doing so. He ordered specific depths and turns, which the OOD-2 repeated to the diving officer and the helmsman. As the captain of the submarine, the CO had the authority to assume the conn.[41] However, by removing himself as backup to and overseer of the OOD-2, the CO eliminated a measure of safety redundancy that the Navy had developed for operations.

During the high-speed turns, which lasted between 5 and 6 minutes, the sonar display was scrambled, making it difficult if not impossible for the sonar crew and the FTOW to determine the accuracy of the contact picture. About 1331, as the submarine was beginning to slow on course 340°, the CO abandoned the checks and balances stipulated in his standing orders and started taking procedural shortcuts that adversely affected the ability of his crew to improve their contact awareness, thereby jeopardizing the safety of the cruise. He ordered the OOD-2 to complete preparations to go to periscope depth within 5 minutes, which the CO said even a veteran OOD would probably have difficulty accomplishing.

The OOD-2 attempted to complete the preparations for going to periscope depth, an involved process requiring him to conduct several tests, instrument checks, and, perhaps most important, a briefing with key watchstanders to share information about the sonar contacts. Through this vital communications step with the sonar supervisor, the FTOW, the radioman, the ESM, and the navigation supervisor, the OOD-2 could have ascertained whether the conn needed to order additional movements to improve the TMA.

Meanwhile, the CO had left the conn to go into sonar, where he watched the monitors as two contacts, S-12 (bearing 316.6°) and S-13 (bearing 016.3°), reappeared, respectively, at 1332:03 and 1332:48. He later stated that the displays led him to believe that the contact picture had not changed, whereupon he returned to the control room.

---

[41] Navy operating procedures stipulate that the CO announce when he is assuming the conn and that the conning officer (in this case, the OOD-2) announce, "The captain has the conn" to the watchstanders, and "Sir, I have relinquished the conn" to the CO.

The *Greeneville* was arriving at 150 feet, the depth at which the OOD-2 reasonably would order TMA maneuvers, when the CO returned to the conn about 1333 and immediately ordered a course change to 120° to clear the baffles. The CO's actions of interrupting the OOD-2 and reassuming the conn resulted in the OOD-2 not holding the required briefing to discuss the contact environment. Again, the CO did not discuss the contact situation with the OOD-2. For his part, the OOD-2 did not speak up and advise the CO that he had not been able to determine whether additional TMA was warranted. Thus, the two officers again failed to communicate necessary information to one another that would have pointed out the need for improved contact awareness.

The CO's order to change course meant that he allowed the *Greeneville* to remain on the 340° leg less than 2 minutes (1331:36 to 1333:03), rather than the 3 minutes stipulated for TMA in Navy operating procedures. More important, the submarine was on a steady speed and course (to 340°) less than 25 seconds before the course change to 120° began. The baffle clear turn was complete about 1335; however, the CO then ordered the submarine to proceed to periscope depth at 1336:45. Consequently, he did not hold course long enough on either the 340° leg or the 120° leg to permit good TMA, a serious error.

The Safety Board constructed a hypothetical *Greeneville* track, extending the 340° and the 120° legs to 3 minutes each to allow for proper TMA. Figure 15 superimposes the hypothetical track over the actual *Greeneville* track. As shown in the chart, the too-rapid course changes on the actual track resulted in no bearing rate change, which is necessary for accurate identification of the contact's course.

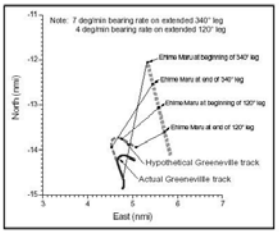

Figure 15. Comparison of *Ehime Maru* bearings with *Greeneville*'s actual track and with hypothetical track calculated for 3-minute legs.

The hypothetical track using 3-minute legs produced bearing rate changes that would have readily revealed the course of S-13 to both the sonar crew and the FTOW. The *Greeneville*'s bearing to the *Ehime Maru* on the hypothetical 3-minute legs would have been as follows:

Beginning of 340° leg.....012.1°
End of 340° leg.....033.0°
Beginning of 120° leg.....050.1°
End of 120° leg.....061.8°

The Safety Board determined that the rate of bearing change would have been about 7° per minute on the 340° leg and 4° per minute on the 120° leg if the legs had lasted the required 3 minutes. Thus, the total S-13 bearing change that the *Greeneville* crew could have obtained if the submarine had stayed on each of the TMA legs for 3 minutes is about 50°, as opposed to a bearing change of about 10° for the actual leg. Such a large bearing change and accompanying rate of bearing change would have alerted the sonar crew and the FTOW to the close proximity of S-13 (the *Ehime Maru*). Moreover, the large bearing changes would have provided sufficient input for the FTOW to develop a high-confidence solution for S-13 that would have placed it nearby and closing.

The CO's conning of the vessel compromised the ability of the combat systems crew to verify the contact picture in other ways. The turn that he ordered for the baffle clear put one of the known sonar contacts, S-12, bearing 316.5°, into the baffle area, the result being that sonar lost the track on the vessel. During the turn, sonar gained S-14, bearing 358°, a potential threat contact to the submarine. The FTOW, having no solution on S-14 and believing that S-13, now 4,200 yards away, was not operating near the *Greeneville*, began to concentrate on S-14 to the exclusion of S-13. However, he could not resume determining solutions for the contacts until the submarine steadied on course 120°, about 1334.

Meanwhile, the CO did not respond appropriately to the sonar supervisor's announcements about the loss of S-12 and the gain of S-14 by determining either their status or whether he needed to conduct additional TMA. Possibly he did not hear the sonar announcements, or perhaps he did not recognize the implication of sonar announcing the loss of one contact and the gain of a new contact. The CO later told Safety Board investigators that he probably would not have made the errors that he did if the AVSDU had been working and he had been able to refer to the sonar repeater.

The CO's comments reflect an operating failure that existed on board the *Greeneville* during this underway. Neither the CO nor the senior members of the combat systems team (OOD-2, sonar supervisor, and FTOW) demonstrated effective ORM when compensating for the inoperable sonar repeater in the control room and for the presence of the civilian visitors near key watchstations. ORM is a decision-making tool used by the Navy and other organizations to increase operational effectiveness by identifying potentially hazardous conditions and adopting procedures aimed at reducing or mitigating the potential for loss. On the *Greeneville*, the standard procedure for compensating for

the loss of the AVSDU was for the conning officer to periodically visit the sonar room to assay the contact picture. However, the OOD-2 never visited the sonar room after conducting his prewatch checks.

The CO chose to compensate for the loss of the AVSDU by twice visiting the sonar room and reviewing the monitors there. Upon returning to the conn after his second visit to sonar, he ordered a course change to 120° to clear baffles about 1333. About the same time that the CO was explaining the purpose of a baffle clear to the civilian visitors, sonar gained S-14 at 1333:03. Thus, the CO may not have recognized that the sonar supervisor was announcing a new contact. The CO's possible error as well as the failures discussed later in this analysis, under "Management of Civilian Visitors," demonstrates that the combat systems team should have assessed the combined impact on operations of the inoperable AVSDU and the presence of civilians near the fire control station and the conn and devised better methods for communicating contact information to the conning officer.

Before the *Greeneville* rose to periscope depth, the CO announced to everyone in the control room that he had a "good feel" for the contacts, which had the effect of discouraging backup from his crew. The inexperienced OOD-2 acquiesced to the more experienced commanding officer, and the seasoned FTOW discounted a solution at his fire control station indicating that S-13 (the *Ehime Maru*) was 4,000 yards away or less. The XO, who had told the OOD-2 that he would go to sonar and relay contact information to him, said nothing to either the OOD-2 or the CO to ensure that the conn had accurate information about the contacts.

The CO continued to rush, pushing his crew and truncating recommended steps for safe operation. While at periscope depth, he interrupted the OOD-2's periscope sweep and took over operating the periscope, executing only a few brief sweeps in the general area where he believed the sonar contacts to be. The CO then ordered the submarine to a shallower depth (from 60 feet to 58 feet), raising the periscope 2 feet for a greater height of eye. On this day, the seas were choppy, 3 to 4 feet; the sky was not clear. The CO either failed to recognize the need to compensate more for the choppy seas and the haze or simply did not do so. He did not order the submarine to a shallower depth for a significantly better height of eye and he did not execute a slower, more deliberate sweep to ensure that no vessels were obscured by the haze. Once again, he did not use his crew resources and solicit the feedback or assistance necessary for safety. Normally during the CO's periscope sweep, the FTOW would assist him in putting the periscope on the precise bearings of the sonar contacts, a standard procedure that improves the probability of detection. On this day, the CO did not ask for assistance, and the periscope was not centered on the contacts' bearings.

The crew's behavior immediately preceding the collision suggests that their errors were strongly influenced by the CO's announcement about the contact picture. In effect, the CO's flawed situational awareness regarding the proximity of vessels at the surface reinforced and influenced the watchstanders' own limited situational awareness. The CO was well regarded by his crewmembers, as evidenced by, among other things, the *Greeneville*'s high retention rate, but his popularity may have worked against optimal

crew performance. That is, because of his rank and the respect among the crew that he commanded, his crew appeared to have acted as though they believed that if the CO thought the surface was clear, it was.

The two-way communication necessary for effective bridge resource management[42] was not evident on the *Greeneville*. The COMSUBPAC Deputy Chief of Staff for tactics and training told Safety Board investigators,

> The watchstanders had sort of an inherent trust in their commanding officer; they didn't speak up when they should have. [They believed that] . . . if the captain thinks it's okay to go up, who am I to stand in front of him and tell him it's not right, and they kind of just rolled on the captain's decision to go up.

If crewmembers disagreed with the CO's assessment, none spoke up to provide him essential feedback, particularly in the presence of the visitors. Every *Greeneville* crewmember interviewed later by the Navy or by the Safety Board stated that he never doubted the assessment of the CO. After the collision, neither the sonar supervisor nor the FTOW believed that the submarine had struck a contact that they were tracking.

Emergency Surfacing Maneuver Toward Contacts

After his brief periscope sweep, the CO ordered an emergency deep dive. During the submarine's descent, he ordered a course change to 340°. Recorded data indicate a left turn during the dive, consistent with this command. He then announced an EMBT blow, an evolution that he had told the navigator he was going to cancel but later said that he decided to order on the spot for training purposes. Again, the CO's actions demonstrate that he continued to fail to employ ORM during the conduct of this cruise. Navy trainers told Safety Board investigators that the operating instructions pertaining to EMBT blows are classified. They stressed, however, that before executing such an emergency surfacing maneuver, COs should do "additional risk management" to ensure that the watchstanders have good information and existing conditions have been identified.

In the case of the *Greeneville* CO, he took a series of procedural shortcuts rather than perform ORM before executing the EMBT blow. He did not establish effective measures for monitoring the sonar contacts. He did not ensure that effective TMA had been accomplished. He abandoned or truncated measures designed to promote safety redundancy in operations, including his proper oversight role of the conning officer and his conduct of the second periscope sweep. He did not use his crew resources effectively to ensure that he obtained good feedback about the operating environment.

[42] Bridge resource management, or BRM, is an operational mechanism for ensuring the safe completion of a vessel's voyage. The Coast Guard requires that operators of certain vessels, such as tankers, employ BRM, and the International Maritime Organization recommends that training for seafarer certification include BRM. (See *International Convention of Standards of Training, Certification and Watchkeeping for Seafarers, 1978*, as amended in 1995.)

The CO's actions after ordering the EMBT blow indicate that he added the emergency evolution for the benefit of the civilian visitors. For the evolution, he paid particular attention to ensuring that the civilian visitors were involved in it. He personally assigned one civilian to sit at the helm controls and allowed another to operate the levers at the high-pressure air controls, albeit under the supervision of experienced crewmembers. He then narrated what was happening during the submarine's ascent for the information of the passengers.

The EMBT blow maneuver requires that a vessel's rudder be centered. Recorded data show that as the EMBT blow maneuver began, the vessel's turn rate slowed, consistent with a rudder centering. At the beginning of the EMBT blow, the submarine's heading was 025°. Thus, the CO's conning order was a serious error that resulted in the submarine pointing in the direction not only of S-13, bearing 018°, but also S-14, bearing about 358°.

As the *Greeneville* rose at a high speed, its heading continued to change slowly and was at 018° when the *Greeneville* struck the *Ehime Maru*, slicing open the bottom of the fishing vessel's hull.

Management of Civilian Visitors

In this case, the civilian visitors did not directly cause the accident; however, their presence on the submarine and the manner in which they were accommodated by the crew, especially the CO, had an adverse impact on the safety of operations.

The *Greeneville* cruise on February 9 was conducted contrary to COMSUBPAC instructions, which stipulated that distinguished visitor embarkations "must be scheduled and conducted within the framework of otherwise planned underway operations, and should not be conducted solely to accommodate civilian guests." The *Greeneville* had been scheduled to begin an underway for testing on February 9, and the civilian guests had been scheduled to ride the submarine during the first day of that underway. However, at the suggestion of the *Greeneville* CO, COMSUBPAC had delayed the start date for the test voyage until February 12 and had granted the *Greeneville* CO permission to take the civilian visitors on a 1-day voyage on February 9.

The unintended effect of permitting such a cruise was that the crew did not demonstrate the attention to detail that they reportedly had exhibited during previous underways and training exercises. They either adopted a somewhat informal attitude toward their duties or concentrated on accommodating the visitors to the detriment of their work.

In the findings from the Navy's court of inquiry, officials found fault with the senior crew's preparation of the watchbill for the visitor cruise. The Safety Board considered whether the poorly prepared watchbill and the crew's subsequent switching of watch assignments were factors in the accident and found that in all but one case, key watch stations were manned by qualified crewmembers. Only sonar lacked a required watchstander: an over-instructor to monitor the qualifying technician. Considering that

the *Greeneville* rarely held more than three contacts, the sonar supervisor could have easily monitored the qualifying technician. However, he could not properly oversee the qualifying technician and efficiently perform his own duties while accommodating the civilian visitors. As evidence of this, he forgot to reset the sonar recorder after playing sound tapes for the enjoyment of the visitors. He also either did not observe the visitors distracting his crew or did nothing to prevent it once the demanding evolutions began.

According to an off-duty sonar technician, when he returned to the sonar room about the time of the angles and dangles, several civilian guests were in the sonar room, in addition to the sonar supervisor, the broadband stack operator, and the workload share stack operator. He said that he noticed that the sonar supervisor and the sonar technicians were trying to talk to each other and the guests at the same time. The off-watch sonar technician said that the sonar operator at the broadband stack appeared not to be distracted by questions from the guests. The unqualified workload share stack operator, however, was trying to answer the visitors' questions. At one point, the workload share stack operator started to turn away from the display to talk with the guests, but the off-watch technician indicated to him that he should watch the display. The off-watch sonar technician said that he then asked the visitors to leave the sonar room. While it is commendable that the off-watch sonar technician took action to improve the operating environment for the sonar crew, the sonar supervisor should have recognized the distraction that the visitors might pose to the watchstanders and asked the civilians to leave the sonar room before the evolutions began.

Interaction with the guests created scheduling problems and changed the operational dynamic in the control room. The *Greeneville*'s activities for the visitor cruise, as listed on the plan of the day, remained reasonably on schedule until first the CO and then the XO each hosted a civilian group at lunch for an hour instead of the time allotted. The CO testified at the court of inquiry and later told Safety Board investigators that he realized that the submarine would be late returning to PJH because of the delay caused by the long lunches; however, he said that he did not rush the conduct of the evolutions to try and return the visitors on time. He indicated that if he had felt rushed, he would not have continued to sign souvenir photographs in his stateroom, but would have gone into the control room sooner to begin the evolutions. In his 2003 autobiography,[43] however, he indicated that his rushed actions during the evolutions were driven by his knowledge that the civilian visitors needed to be back at Pearl Harbor by a given time for a later appointment.

In the control room, the CO's management of and interaction with the visitors created both physical and communication barriers for his subordinates. After he advised the civilians where to stand for the best vantage point of the upcoming evolutions, six to eight visitors stood on the starboard side of the periscope platform, blocking the FTOW's ready access to the CEP, which the FTOW was required by standing order to annotate to provide the conning officer with a display of the submarine's position relative to the position of known vessel contacts. The FTOW said that he stopped maintaining the CEP

[43] S. Waddle and K. Abraham, *The Right Thing* (Nashville: Integrity Press, 2003).

because of the presence of the visitors. Given that the visitors also blocked the conning officer's view of the CEP, the FTOW's failure to perform this watch task did not affect the outcome of this accident because neither the OOD-2 nor the CO attempted to review the chart.

Some of the civilians stood in front of two fire control system displays that the OOD-2 used to monitor the contact situation. The OOD-2 later told Safety Board investigators, "I didn't have free access all the way over there."

Although the civilians impeded their work, neither the OOD-2 nor the FTOW asked them to move or told the CO that the visitors were adversely affecting operations. The CO was focused on directing the activities for the civilians rather than managing the civilians to ensure that they did not interfere with the watchstanders' execution of their duties. As a result, the FTOW was reluctant to speak up and interrupt him. Thus, the activities for the civilian visitors stymied communication and prevented the conn from receiving necessary feedback from the crew.

As a result of the Navy's court of inquiry, in August 2003, COMSUBPAC issued new procedural requirements (COMSUBPACINST 5720.1) for handling in-port public visits and embarkations on Pacific Fleet submarines. The COMSUBPAC instructions include provisions designed to ensure not only that visitors remain safe but also that crew operations are not compromised during a civilian embarkation. The crewmembers assigned to oversee the civilian visitors while they are on the submarine must be listed as escorts on the watchbill and they cannot be assigned to a workstation. The CO or his agents are to review the itinerary developed for the visitors for areas of "conflict," for example, areas where overcrowding might occur when all or several civilians are present.

Recommended procedures include conducting the initial visitor briefing in the mess facility during the outbound transit so that the piloting party can function without distraction. To ensure that the control room is not overcrowded during evolutions, the instructions recommend that the plan of the day include two surface and dive evolutions, so that a visitor group can be divided and fewer civilians permitted in the control room at one time. To ensure that the crew is not distracted while making preparations to go to periscope depth, the instructions recommend that the visitors be taken to the mess facilities, where they can watch a movie or a monitor linked to the PERIVIS.

In addition to revising procedures directly related to visitor cruises, the Navy made changes in squadron oversight designed to address safety deficiencies that the Safety Board also noted in its investigation. For several reasons, the *Greeneville* was not subject to the type of oversight that should have revealed shortcomings in the crew's adherence to Navy operating procedures. Factors affecting squadron oversight included removal of the *Greeneville* from the regular deployment rotation when it was equipped with an Advanced SEAL Delivery System, realignment of the squadron and the resulting reduction in oversight personnel, and demands on the newly appointed squadron commander who was given the priority to prepare another submarine for deployment.

The development and implementation of effective operating procedures for all phases of operations is a prerequisite for the safe operation of any vessel, military or civilian. Operating procedures in and of themselves, however, are insufficient to ensure safety unless they are accompanied by systematic oversight of their use by crewmembers or workers in regular operations. Effective oversight provides information not only about how individuals use or comply with operating procedures but also about whether the procedures, as written or established, are effective in an actual operating environment.

As a result of the *Greeneville* accident, the Navy changed its method of evaluating submarines, regardless of their deployment cycles. The squadrons now employ a multistep evaluation process that includes, among other reviews and tests, a basic evaluation of the submarine crewmembers to determine their fundamental understanding of their jobs and responsibilities; identification of procedural problem areas or weaknesses and follow-up monitoring by squadron officials; and a second formal review to check a ship's readiness to deploy.

The changes in squadron oversight procedures as well as the new requirements for distinguished visitor cruises demonstrate that the Navy has recognized the detrimental operating conditions that existed on board the *Greeneville* and has taken additional measures to address the safety of operations on board its submarines. Accordingly, no further action is warranted.

Survivability of the Ehime Maru

The design of the *Ehime Maru* was typical for a ship of that size and service. In addition to meeting industry standards for strength, the ship was fitted with transverse bulkheads and a double bottom in the engineroom to provide a measure of flotation and stability in the event of moderate damage from collision or grounding. This is typical of modern ship design, and the standards reflect historical experience with damages and international consensus on a reasonable degree of protection that should be provided. The damage sustained by the *Ehime Maru* far exceeded the criteria used for design, and the simultaneous flooding of several watertight compartments immediately doomed the ship. The damage scenario is so unusual and extensive that it is considered impractical to modify the basis of watertight design for ships of this size. Accordingly, this accident does not constitute a reason for review or revision of international standards of subdivision and damage stability.

Probable Cause

The National Transportation Safety Board determines that the probable cause of the collision of the USS *Greeneville* with the Japanese fisheries training vessel *Ehime Maru* was the inadequate interaction and communication among senior members of the combat systems team (the commanding officer, the officer of the deck, the fire control technician, and the sonar supervisor), which resulted in the failure to perform adequate contact analysis and adhere to proper procedures for moving to periscope depth; and the commanding officer's decision to order an emergency surfacing maneuver. Contributing

to the cause of the accident was the failure of the crew, in particular the commanding officer, to adequately manage the civilian visitors so that they did not impede operations. Contributing to the loss of life was the rapid flooding and sinking of the *Ehime Maru*, which occurred when the submarine's rudder tore through the fishing vessel's lower deck spaces.

Adopted: September 29, 2005

Appendix A

Investigation

The National Transportation Safety Board learned of the *Greeneville/Ehime Maru* accident at 2118 on February 9, 2001, from news media reports. The Safety Board initially launched a five-person investigative team from the Office of Marine Safety, including the chief of the technical services division, an investigator-in-charge, an engineering specialist, a human performance specialist, and a survival factors specialist. A Board Member and representatives from the Safety Board's Office of Government, Public, and Family Affairs joined the team, and the group arrived in Honolulu about 1545 on Saturday, February 10, 2001. A naval architect and an aircraft structures specialist who was proficient in underwater recovery efforts subsequently joined the team. The naval architect documented the damage to the vessels, and the recovery specialist served as liaison to the Navy salvers.

The Safety Board investigated the accident under the authority of the Independent Safety Board Act of 1974, as amended, according to the Safety Board's rules. Team members interviewed the survivors of the *Ehime Maru* between February 11 and 13, 2001. The team also interviewed Coast Guard personnel involved in the search and rescue, emergency medical services officials, the American Red Cross supervisor, and the harbor pilot who took the *Ehime Maru* out of Honolulu. The Safety Board began interviewing crewmembers of the *Greeneville* on February 13, 2001. However, at the time, the CO, the XO, and the OOD-2 declined to assist in the Safety Board's accident investigation. These three officers were eventually interviewed by Safety Board investigators, as indicated below:

- September 2001—the OOD-2
- November 2001—the XO
- March 2002—the CO

The Safety Board also interviewed the commanders of Squadrons 1, 3, and 7, the instructor of the prospective commanding officers course, and the COMSUBPAC Deputy Chief of Staff for tactics and training in March 2002, and the former COMSUBPAC in May 2002.

The designated parties to the Safety Board's investigation were the U.S. Navy, the U.S. Coast Guard, and Ehime Prefecture, Japan, owner of the *Ehime Maru*.

Appendix B

Abbreviations and Acronyms

AVSDU	Analog-Video Signal Display Unit
CEP	contact evaluation plot
CO	commanding officer
COMSUBPAC	Commander, U.S. Submarine Force, Pacific (also command office for U.S. Submarine Force, Pacific)
EMBT	emergency main ballast tank
EPIRB	emergency position indicating radio beacon
ESM	electronic support measures
FAA	Federal Aviation Administration
FTOW	fire control technician of the watch
MHz	megahertz
OOD	officer of the deck (Note: in this report, the OOD of the second underway watch is referred to as the OOD-2)
OP	operations procedure
OPNAVINST	Chief of Naval Operations instruction
OPORD	operations order
ORM	operational risk management
PERIVIS	periscope video system
P/H	"Poppa/Hotel," the unmarked seaward entrance to Pearl Harbor
RHIB	rigid hull inflatable boat
SECNAVINST	Secretary of the Navy instruction
SLOGGER	sonar data logger
SNR	signal-to-noise ratio
SOLAS	International Convention for the Safety of Life at Sea
TMA	target motion analysis
UTC	Universal Coordinated Time
XO	executive officer

Appendix C

Chronology of Events, February 9, 2001

Accident Events

Time	Activity
Pre-0500	*Fire control officer of the watch* (FTOW) checks fire control equipment in control room and finds that everything operates correctly.
Pre-0700	Navigator reports to commanding officer (CO) that the control room's Analog-Video Signal Display Unit (AVSDU), which provides a backup display of sonar data, is inoperative.
0730	CO greets 16 distinguished visitors at dockside as they board the *Greeneville* at Pearl Harbor. The distinguished visitors are assembled in the crews' mess, where they are given a brief presentation, including a slide show, about the submarine. They are broken into two groups for tours of the vessel.
0757	*Greeneville* departs berth.
0903	Navigator assumes watch as officer of the deck (OOD).
1017	*Greeneville* submerges.
1045	CO joins first group of distinguished visitors for lunch at first seating, which is from 1045 to 1145.
1054	Deep dive.
1103-1131	Dive to classified depth.
1130	Underway watch change scheduled. FTOW assumes watch at fire control console. Sonar supervisor assumes watch in sonar room.
1143	Main propulsion assistant assumes watch as officer of the deck (OOD-2) in the control room.
1145	Executive officer (XO) joins second group of distinguished visitors for lunch at second seating, which is from 1145 to 1245.
1200	Sonar supervisor, in preparation for planned maneuvers, checks sonar stack for loose gear. *Ehime Maru* departs Honolulu.
1207	OOD orders course change to north (000°).
1228:59	Sonar begins tracking contact Skorpa 12 (S-12).
1231:59	Sonar begins tracking contact S-13, bearing 358° (the *Ehime Maru*).
1232:59	Fire control system automatically generates first solution for S-13.
1240	OOD-2 orders baffle clear.
1242:16	*Greeneville* changes course to 240°, and sonar drops tracks on both S-12 and S-13 when they enter the baffle area.

Time	Activity	
1245	*Greeneville* resumes northerly course.	
1257	*Ehime Maru* completes stowing anchor and increases speed to 11 knots.	
1306+/-	XO advises CO that ship needs to start maneuver demonstrations if submarine is to meet the distinguished visitors' scheduled return time to Pearl Harbor.	
1310+/-	Visitors enter control room; CO goes into sonar room to assay contact picture. Observes two contacts (S-12 and S-13) to the north and northwest.	
1314	CO enters control room and talks with visitors, advising them of the best locations to observe the submarine's maneuvers.	
1315	*Greeneville* increases speed to 14 knots and begins angle maneuvers ranging in depth from 150 to 650 feet.	
1315-1324	Sonar supervisor and sonar operators, while attempting to track targets, interact with five visitors who enter the sonar room.	
1324+/-	Sonar technician who returns to get his jacket asks visitors to leave the sonar room before *Greeneville* begins rudder maneuvers, or high-speed turns.	
1325	CO directs OOD-2 to order the following turns during the high-speed maneuvers: *Greeneville* to turn right from a course of 000° right to 140°.	
1328:27	*Greeneville* is steady on 140°.	Time steady on course until next turn: 16 sec.
1328:43	*Greeneville* to turn left to 340°.	--
1328:04	*Greeneville* is steady on 340°.	Time steady on course: 23 sec.
1328:27	*Greeneville* to turn right to 120°.	--
1329:47	*Greeneville* is steady on 120°.	Time steady on course: 23 sec.
1330:42	*Greeneville* completes high-speed maneuvers and comes left to 340°.	
1331+/-	CO directs OOD-2 to prepare to go to periscope depth and to be there within 5 minutes.	
1332	CO goes into sonar a second time to determine contact picture; watches as sonar regains S-12 at 1332:00 and S-13 at 1332:45.	
1332:54	*Greeneville* arrives at 150 feet from a depth of 400 feet.	Total time above layer depth" is 91 seconds.
1333	CO returns to control room; directs OOD-2 to order a baffle clear to course 120°.	
1333:00	Sonar begins tracking S-14.	
1334:48	Tracking solution entered for S-14; S-12 fades.	
1335	Baffle clear complete. OOD-2 orders sonar to report all contacts; sonar reports S-13 and S-14.	
1336	CO announces that he has "good feel" for contact picture (later stated that he thought the contacts were S-12 and S-13).	

APPENDIX H

Kaka'ako Makai Vision and Guiding Principles
Kaka'ako Makai
Community Planning Advisory Council (CPAC)

Time	Activity
1328-45	CO orders ship to periscope depth (60 feet).
1327-49	As submarine ascends, fire control solution is updated, assuming 5-13 [fire Zrime Navy] is within 4,000 yards.
1328	Submarine periscope breaks surface of water.
1328	COD:2 conducts three rapid 360° periscope sweeps and reports "No close contacts" Under-instruction operator in ESM room reports "No close contacts" to fire-cons.
1328-04	CO takes periscope from COD:2 and orders the ship to 56 feet.
1328:30	CO conducts periscope search in the direction where he believes S-12 and S-13 to be.
1340-+/-	CO orders emergency deep. Total time at periscope depth: 60 sec.
1340	8-14 knots.
1340+	As submarine begins to descend, CO asks quartermaster the course to PIH. Quartermaster responds 340°, and CO orders him to 340°.
1340-34	Submarine starts to come left from 121° to 340°.
1342-35	Unnamed/e attains EMBT.
1343 15	Unnamed/e crashes with Crime Navy. (Approximate bearing of submarine is 070°.)

Type depth is the depth from the surface of the sea to the point where the first major negative thermocline (area of rapid decrease in water temperature) or much sound velocity is measured.

Search-and-Rescue Events

Time	Event
1343	Collision occurs.
1345	Crime Navy sinks.
1345	Unnamed/e begins maneuver.
1345	Unnamed/e radios report of collision to COMSUBPAC.
1355	COMSUBPAC reports collision to Coast Guard Group–Honolulu.
1355	Coast Guard Group–Honolulu divverts helicopter No. 65/D from patrol to scene.
1355	Group–Honolulu directs Coast Guard Station–Honolulu to launch rescue assets.
1400	Station–Honolulu dispatches rigid hull inflatable boat (RHIB) and a patrol boat to scene.
1400	Joint Rescue Coordination Center receives signal from Crime Navy's EPIRB.
1404	Joint Rescue Coordination Center identifies vessel as Crime Navy.
1405	Joint Rescue Coordination Center contacts Coast Guard Group–Honolulu to investigate.
1420	COMSUBPAC calls Joint Rescue Coordination Center.
1427	Coast Guard helicopter No. 65/D arrives on scene.
1431	Coast Guard RHIB arrives on scene.
1444	Coast Guard patrol boat arrives on scene.
1445	Coast Guard helicopter No. 60/D transfers its rescue swimmer to patrol boat.
1445	COMSUBPAC advises two torpedo maneuver boats, Aaamcrone 3 and Aaamcrone 8.
1446	Coast Guard helicopter No. 65/D begins area search.
1451	Coast Guard debriefs C-130 aircraft from training to scene.
1505	Joint Rescue Coordination Center assumes control of search-and-rescue mission.
1524	Coast Guard C-130 plane arrives and assumes on-scene command.
1535	Coast Guard RHIB and patrol boat depart scene with 26 survivors.
1615	Rescue vessels arrive at Coast Guard Station–Honolulu.

NOTE: Search for missing crewmembers continued between February 9 and March 2. Crime Navy was located on the seafloor in 2,000 feet of water on February 10.

KAKA'AKO MAKAI COMMUNITY PLANNING ADVISORY COUNCIL

THE VISION FOR KAKA'AKO MAKAI

The Hawaiian Place of Ka'akaukukui and Kukuluae'o

Kaka'ako Makai is the community's gathering place. A safe place that welcomes all people, from keiki to kūpuna, with enriching cultural, recreational and educational public uses. A special place that continues the shoreline lei of green with scenic beauty, connects panoramic vistas mauka to makai, and encourages ecological integrity of land, air and sea. Kaka'ako Makai honors, celebrates and preserves its historic sense of place, Hawaiian cultural values and our unique island lifestyle for present families and future generations.

GUIDING PRINCIPLES

Community Cultural Gathering Place

Establish Kaka'ako Makai as a gathering place where community and culture converge in response to the natural scenic beauty of the green shoreline open space.

- *Celebrate the intertwined cultures of the community by ensuring a welcoming gathering place for a broad cross-section of people diverse in age, income and ethnicity.*
- *Provide enriching public recreational, cultural and educational opportunities for residents and visitors alike through Kaka'ako Makai's scenic coastal and marine environment, the Native Hawaiian cultural heritage, compatible facilities and activities, and historic sites and settings.*

Hawaiian Culture and Values of the Ahupua'a

Base the framework for planning, decision-making and implementation of the Kaka'ako Makai master plan on Native Hawaiian values and traditional and customary rights and practices protected by the State.[1]

- *Emphasize the host Hawaiian culture.*[2]
- *Incorporate the ahupua'a concept and spirit of caring for, conserving and preserving the self-sustaining resource systems necessary for life, including the land that provides sustenance and shelter, the natural elements of air, wind and rain extending beyond the mountain peaks and streams of pure water, and the ocean from the shoreline to beyond the reef where fish are caught.*
- *Adopt the ahupua'a lifestyle of individual kuleana working together and contributing to the whole for a greater level of stewardship, conservation, and proper management of resources with contemporary land-use benchmarks, such as growth boundaries and carrying capacity.*
- *Assure that the planning of collective or individual traditional features, settings, and activities will be overseen by Hawaiian historic and cultural experts to prevent misinterpretation or exploitation.*

[1] Hawaii State Constitution, Article XII, Section 7. Inform the planning process by the principles and traditions of the ahupua'a, and inspire the master plan by the interconnected relationship of people.
[2] §206E-34(c)(5), Hawaii Revised Statutes. The Hawaiian host culture is emphasized as pre-eminent yet inclusive of other cultures.

Open View Planes

Protect, preserve and perpetuate Kaka'ako Makai's open view planes from the mountains to the sea as an inherent value of the Hawaiian ahupua'a and an important public asset for residents, visitors and future generations.[3]

- *Ensure planning and development safeguards to identify, document, retain, restore and protect makai-mauka and diamondhead-ewa open view planes to the Ko'olau mountains, Diamond Head (Lē'ahi) and the Wai'anae mountains as seen from the view vantage areas and vicinities of Kaka'ako Makai's public lands and Kewalo Basin Harbor.*

Coastal and Marine Resources

Preserve, restore and maintain Kaka'ako Makai's valuable coastal and marine resources for present and future generations.

- *Enable the monitoring, protection, restoration, and conservation of natural coastal and ocean resources, including reef and marine life, through responsible stewardship and sustainable practices.*
- *Protect and sustain the coastal environment for cultural uses including fishing, ocean gathering, surfing and ocean navigation.*

Expanded Park and Green Space

Ensure expansion of Kaka'ako Makai's shoreline parks as significant landscaped open spaces[4] *joining the lei of green parks extending from Diamond Head (Lē'ahi) to Aloha Tower.*

- *Implement the Hawaiian values of the ahupua'a and mālama 'āina by preserving shoreline open space, protecting scenic coastal and marine resources, and respecting the natural interaction of people, land, ocean and air.*
- *Welcome residents and visitors alike with green open space, abundant shade trees and opportunities for family recreation.*
- *Use the established park planning standard of at least 2 acres per 1000 residents as a benchmark to assure sufficiency of park space to contribute to the health and welfare of Kaka'ako Mauka's growing population and offset increased urban density, noise and pollution.*

Public Accessibility

Provide open and full public access to recreational, cultural and educational activities within and around Kaka'ako Makai's parks and ocean shoreline.

- *Ensure complete public recreational access with minimal impact to the environment, including drop-off accommodation of ocean recreation equipment and connections to public transportation.*
- *Provide a shoreline promenade and tree-lined paths to safely and comfortably accommodate pedestrians, bicyclists and the physically impaired.*
- *Provide sufficient shared parking complementary to the natural setting to support all uses in Kaka'ako Makai, with workplace parking available for recreational and cultural users during non-working hours.*

[3] Significant Panoramic Views Map A-1, Honolulu Primary Urban Center Development Plan.
[4] Inclusive of Kewalo Basin Park, Kaka'ako Waterfront Park and Kaka'ako Gateway Park.

Public Safety, Health and Welfare

Ensure that Kaka'ako Makai is a safe and secure place for residents and visitors.

- *Keep public use areas safe day and night for public comfort and enjoyment.*
- *Ensure that exposure to land and ocean is environmentally safe for people and marine life by assuring timely investigation, determination, and remediation of contaminates.*
- *Ensure that Kaka'ako Makai remains free and clear of elements, activities and facilities that may be potentially harmful to the natural environment and public well-being, including laboratories containing and experimenting with Level 3 or higher bio-hazardous pathogens and/or biological toxins known to have the potential to pose a severe threat to public health and safety.[5]*

Public Land Use Legislation –
Public Use of Public Lands in the Public Interest

Recognize and respect the effort and intent of the Hawaii State Legislature to uphold the greater public interest by ensuring and sustaining public uses on Kaka'ako Makai State public lands for the greater public good.

- *Preclude the sale of public land and development of housing in Kaka'ako Makai;[6]*
- *Demonstrate commitment to serve the highest needs and aspirations of Hawaii's people and the long-term good of Hawaii's residents and future generations through community-based planning;[7]*
- *Restore the site-dependent use of Kewalo Basin Cove to the Kewalo Keiki Fishing Conservancy.[8]*

Kewalo Basin

Ensure that Kewalo Basin Harbor's unique identity is retained with continued small commercial fishing and excursion boat uses, keiki fishing and marine conservation, marine research and education, and accessible green park open space expanding the lei of green between Ala Moana Park and Kaka'ako Waterfront Park.

- *Enable continued functional commercial boating uses at Kewalo Basin Harbor[9] and preserve the beneficial relationships between the existing small commercial fishing and excursion boat businesses and land-based maritime support service businesses.*
- *Ensure that Kewalo Basin will continue as a State of Hawaii commercial harbor and valuable public facility asset by repairing, maintaining and enhancing the harbor for small commercial fishing and excursion boat use.*
- *Ensure the protected use of Kewalo Basin Cove for Kewalo Keiki Fishing Conservancy keiki fishing and marine conservation programs.*
- *Support Kewalo Marine Laboratory's continued valuable marine biology and ecosystems research and education in the vicinity of Kewalo Basin.*
- *Ensure preservation of Kewalo Basin Park, the net house and parking lot for public use, upgrade and improve existing facilities within the park, and provide green open space between Ala Moana Park and the channel frontage.[10]*

[5] Protection of the public health and safety is first and foremost in this area a) immediately adjacent to a Shoreline recreation area and the urban population center, b) in close proximity to a regional beach park and the Waikiki primary visitor destination, and c) within the updated tsunami zone. http://beta.abc3340.com/news/stories/1007/460171.html http://www.nytimes.com/2007/10/05/us/05labs.html?_r=1
[6] §206E-31.5, Hawaii Revised Statutes.
[7] HCR 30, 2006.
[8] Act 3, 2007, Special Session.
[9] §206E-33(2), Hawaii Revised Statutes.

Cultural Facilities

Offer public enrichment opportunities through both fixed and flexible cultural facilities that celebrate the diverse cultures of Hawai'i and blend compatibly with the shoreline open space.

- *Contemplate compatible indoor and outdoor performance venues that encourage the teaching, practicing, and presentation of hula, theater, music, dance, and other performing and visual arts, with an outdoor multi-cultural festival space for Honolulu's diverse ethnic communities.[11]*
- *Contemplate educational facilities, such as an exhibition hall with permanent, interactive and rotating exhibits, museums communicating the cultural history of the area, and places for traditional Hawaiian cultural practices.[12]*
- *Establish a cultural market stocked by local farmers, fishers and Hawaiian traditional craft makers to reflect the Hawaiian values of gathering and trading in the ahupua'a between the mountains and the sea.[13]*
- *Ensure a community center for local families to gather, interact and learn from each other.*

Small Local Business

Apportion a limited number of small local businesses to assist in cooperatively sustaining Kaka'ako Makai's public use facilities.

- *Ancillary small businesses may include diverse local restaurants, cafés, small shops, markets or other uses that will complement the recreational, cultural, harbor or other public facilities serving the community interest.[14]*
- *Encourage small local enterprises that emphasize the Hawaiian culture and support traditional local products, rather than large corporate retailing attractions.*

Site Design Guidelines –
A Hawaiian Sense of Place in Landscape, Setting and Design

Ensure that Kaka'ako Makai's public use facilities are compatible in placement, architectural form, and functional design within the landscape of the shoreline gathering place.[15]

- *Provide and maintain abundant native coastal plants and trees to blend the scenic and sensory qualities of the coastal environment and create a Hawaiian sense of place.*
- *Identify, protect, preserve, restore, rehabilitate, interpret and celebrate Kaka'ako Makai's historic sites, facilities, settings, and locations.*
- *Maintain the quality of coastal environmental elements including natural light, air and prevailing winds.*
- *Mandate sustainability principles, conservation technologies, and green building standards for buildings, grounds and infrastructure.[16]*

[10] Inclusive of greenbelt connections between Ala Moana Park and Kewalo Basin Park, between the Net House and Kewalo Basin Channel, and between Ala Moana Boulevard and Kewalo Basin to Point Panic.
[11] §206E-34(d)(3), Hawaii Revised Statutes.
[12] §206E-34(d)(5), Hawaii Revised Statutes.
[13] §206E-34(a) and (b), Hawaii Revised Statutes.
[14] §206E-34(d)(2), Hawaii Revised Statutes.
[15] Encourage private development mauka of Ilalo Street to compliment the gathering place concept of the Kaka'ako Makai public use area on public lands by providing landscaped set-backs and inviting open architecture at the street level.
[16] Ensure reasonable carrying capacity with limited infrastructure for sufficient water supply, storm-water drainage and waste disposal.

Community/Government Planning Partnership

The Kaka'ako Makai Community Planning Advisory Council places the public interest first and foremost, and will strive to uphold the greater good of the community in partnership with the HCDA as the public oversight agency by:

- *Openly working with the community, the HCDA and the HCDA's planning consultants as guaranteed by government commitment to ongoing community representation and involvement throughout the master planning process;*
- *Openly communicating with the State Legislature and other elected public officials;*
- *Committing the time and effort required to meet the goals and objectives of the Kaka'ako Makai planning process, and advocating responsibly in the public interest both collectively and individually, notwithstanding premature or conflicting proposals.*

Future Funding and Management

Assure and assist viable and sustainable operation of public uses and facilities on State public land in Kaka'ako Makai through public/private partnerships and 501(c)(3) non-profit management[17] similar to successful park conservancies and their stewardship programs.

- *The community land conservancy will be essential in determining safeguards to restore, protect and perpetuate Kaka'ako Makai's natural shoreline resources and view planes, historic and recreational resources, and public uses on State public lands in the public interest as a quality of life benchmark.*
- *This conservancy may be a public/private partnership of the Kaka'ako Makai Community Planning Advisory Council (CPAC), the Hawaii Community Development Authority (HCDA) or current oversight agency, and private contributing interests to both monitor and underwrite public use on State pubic land in service to the public good.[18]*

[17] §206E-34(c)(3), Hawaii Revised Statutes.
[18] A public/private community benefits agreement may be developed upon completion of the master plan to define respective responsibilities and contributions.

INTRODUCTION

1.1 PURPOSE

The purpose of this report is to provide an assessment of transportation impacts that could result from adoption and implementation of the Draft TOD Overlay Plan[1] ("TOD Alternative A"). Where impacts are identified as significant, based on the significance criteria described in this section, the report identifies potential transportation mitigations. The results of this assessment will be incorporated into an Environmental Impact Statement (EIS).

The EIS will assess the impacts of three alternatives: the Future Baseline Condition, TOD Alternative A, and TOD Alternative B. TOD Alternative B was developed as part of a legislative action seeking to examine a lower density alternative to the Draft TOD Overlay Plan (the "TOD Alternative A"). Analysis on TOD Alternative B indicates that this alternative will likely be about 90% of the density in TOD Alternative A. Thus, TOD Alternative A represents the Worst Case Scenario in this transportation analysis. No TOD Alternative B is evaluated in this report due to this fact. It should be assumed that any impact in TOD Alternative B will be less than what is displayed in TOD Alternative A in this report.

Project Location

The project location is shown on Figure 1. The TOD Alternative A encompasses the Kaka`ako Community Development District (KCDD) including the Aloha Tower Special District. The KCDD is comprised of two areas. The first is approximately 450 acres on the mountain (mauka) side of Ala Moana Boulevard, and is bounded by Piikoi Street, Punchbowl Street and King Street. It is hereinafter referred to as the "Mauka Area." The second area in the KCDD is approximately 151.6 acres on the ocean (makai) side of Ala Moana Boulevard. It is bounded by Ala Moana Regional Park and Pier 1 of the Honolulu Harbor, It is hereinafter referred to as the "Makai Area." The Aloha Tower Special District is comprised of approximately 3.4 acres located on the ocean side of Ala Moana Boulevard bounded by Richard Street, Bishop Street and Aloha Tower Drive. The total area addressed in TOD Alternative A is approximately 604 acres.

The KCDD is composed of several sub-neighborhoods, each with its own unique character. With the exception of the Makai District and Aloha Tower Special District, these neighborhoods were defined in the Mauka Area Plan and Rules based on existing and emerging land uses, building forms, and land tenure patterns combined with the influences of major transportation corridors and adjacent districts. Each neighborhood with its own distinct character will be influenced differently from the provisions laid forth in the TOD Alternative A. Recognizing this, the intent of implementing transit oriented development is not to redefine the existing character of the existing neighborhoods, but to utilize TOD to enhance the existing quality of Kaka`ako as a whole.

Kakaako Community Development District TOD Overlay Plan | FEIS Transportation Analysis
Hawaii Community Development Authority

Figure 1 Project Location & Regional Context

1.2 METHODOLOGY

Travel Modes

This transportation analysis provides an assessment of potential impacts to the following modes of transportation:

- Bicycle circulation
- Motor vehicle circulation
- Pedestrian circulation
- Public transit

Analysis Scenarios

The planning horizon for the TOD Overlay Plan is 2035. The transportation analysis is based on a comparison of transportation conditions under each of the following three scenarios:

- **Existing Conditions** –A review of existing multi-modal transportation conditions within the study area based on observations and data collected in 2013.
- **Year 2035 Conditions with No Action (Future Baseline Condition)** – An assessment of future multi-modal transportation conditions in the 2035 horizon year, based on planned transportation network changes and anticipated future development allowable development under the current adopted land use plan for the area. The Future Baseline Condition constitutes "no action" because it represents what will happen in the district under the existing Rules (without implementation of the TOD Overlay Plan).
- **Year 2035 Conditions with TOD Alternative A** – An assessment of future multi-modal transportation conditions in the 2035 horizon year, based on proposed transportation network changes and anticipated development under the TOD Alternative A.

Travel Demand Modeling

The Oahu Metropolitan Planning Organization (OMPO) travel demand model was utilized to develop 2035 travel demand forecasts for purposes of comparing the Future Baseline Condition and TOD Alternative A. Forecasts of total daily travel to, from and within the study area were derived from the model based on the anticipated land use and transportation network changes. Future-year changes to AM and PM peak hour turning movements at key intersections were also derived from the OMPO model, for purposes of comparing AM and PM Peak Hour traffic operations at key intersections selected for analysis.

A detailed breakdown of existing and future land uses, under the Future Baseline Condition and TOD Alternative A, was provided to Nelson\Nygaard for each transportation analysis zone (TAZ) in the project area. Based on that land use data, the OMPO model was updated for purposes of forecasting travel demand based under both the Future Baseline Condition and TOD Alternative A.

1.3 SIGNIFICANCE CRITERIA

For purposes of the environmental impact statement (EIS), transportation impacts are considered significant if the TOD Alternative A results in unacceptable conditions based on local significance criteria. This analysis applies the multi-modal significance criteria that were identified in the *2009 Kaka`ako Mauka Area Plan Supplemental EIS* (2009 SEIS)[ii]. The criteria are as follows:

Motor Vehicle Traffic Impact Criteria

- *The operational impacts on intersections are considered significant if plan-related traffic causes the level of service to deteriorate from LOS E or better under the Future Baseline Condition to LOS F under the TOD Alternative A.*
- *The operational impacts on signalized intersections operating at LOS F under both the Future Baseline Condition and TOD Alternative A are considered significant if the volume-to-capacity (v/c) ratio under the TOD Alternative A exceeds that of the Future Baseline Condition.*

Transit Impact Criteria

- *The operational impacts on transit facilities are considered significant if the plan causes a substantial increase in transit demand that could not easily be accommodated by available transit capacity, resulting in unacceptable levels of transit service. A capacity utilization above 80 to 90 percent is generally considered unacceptable for urban transit services.*
- *The operational impacts on transit facilities are considered significant if the plan causes a substantial increase in operational delay or costs that could result in adverse impacts to transit service.*

Bicycle Impact Criteria

- *The operational impacts on bicycle facilities are considered significant if the plan would create potentially hazardous conditions for bicyclists or otherwise substantially interfere with bicycle accessibility to the site and adjoining areas.*

Pedestrian Impact Criteria

- *The operational impacts on pedestrian facilities are considered significant if the plan would result in substantial overcrowding on public sidewalks, create potentially hazardous conditions for pedestrians, or otherwise interfere with pedestrian accessibility to the site and adjoining areas.*

1.4 PROJECT OVERVIEW

This transportation assessment is based on the Project Description in the Draft Kaka`ako TOD Plan EIS[iii] provided to Nelson\Nygaard on July 3, 2013. The Project Description is summarized below.

Background

In 2005 the HCDA embarked on a comprehensive review of the Mauka Plan and Rules to address livability, urban design and update aging infrastructure needs. This Plan was developed around smart growth concepts, and was adopted in 2011. An environmental impact statement (EIS) was prepared to assess the impacts of the proposed rules. In 2011, the Governor accepted the Final Supplemental EIS for the Draft Mauka Area Plan as fulfilling the requirements of Chapter 343, HRS. The HCDA Board subsequently approved the rules implementing the Mauka Area Plan.

As set forth in the 2011 Conceptual Master Plan for the Makai District, the area of the KCDD makai of Ala Moana Boulevard (and including the Aloha Tower Special District) is envisioned as the community's gathering place that welcomes all people with enriching cultural, recreational, and educational public uses.

In 2012, the Honolulu City Council approved an alignment for the Honolulu Authority for Rapid Transit (HART) elevated light-rail transit system. The alignment identified three transit stations in lands under the authority of the HCDA: two in Kaka`ako and one at the Aloha Tower Special District. In response to this action, HCDA retained consultants to prepare a plan to address the opportunities presented by the introduction of an elevated light rail system in Kaka`ako.

The Draft Transit Oriented Development Overlay Plan (hereinafter, "the Draft TOD Overlay Plan", "the Plan", or "the TOD Alternative A") is a supplementary action that endorses the Comprehensive Plan for the Makai Area (2011), together with the Mauka Area Plan (2011) smart growth objectives. The Draft TOD Overlay Plan further focuses growth with an emphasis on transit-oriented development (TOD), and transit-supportive transportation planning strategies. The Draft TOD Plan's purpose is not to redefine the vision from this earlier effort, but rather, to utilize TOD to enhance Kaka`ako as a whole and the Mauka Area in particular. Related efforts have included station area planning by the City & County of Honolulu along the HART proposed alignment.

Kakaako Community Development District TOD Overlay Plan | FEIS Transportation Analysis
Hawaii Community Development Authority

Figure 2 Kakaako Community Development District (KCDD) & Planned HART Alignment

Future Baseline Condition

The Future Baseline Condition is used to provide a point of departure from which to measure the impacts of the TOD Alternative A. The Future Baseline Condition represents how the KCDD would appear if it were developed in accordance with the prevailing rules by the target year 2035. In other words, it considers the following question: if no action were taken other than the continued implementation of the Mauka Area and Makai Area Rules, what would be the result?

Under the Future Baseline Condition, the KCDD would be built out to the density envisioned by the Mauka Area Plan (2011) and the Conceptual Makai Area Plan (2011). Both the TOD Alternative A and the Future Baseline Condition investigate the capacity of the KCDD at full build out under existing and proposed regulatory environments. The resulting analysis will guide actions to mitigate impacts associated with the implementing ordinance for the Draft TOD Overlay Plan.

The following principles are presented in the Urban Design element of the Mauka Area Plan. They describe the vision for the KCDD in 2035 under the prevailing rules:

- Create an outstanding pedestrian environment.
- Create a network of green streets.
- Provide a maximum of road connections.
- Connect pedestrian paths across major thoroughfare.
- Strong Mauka-Makai linkage.
- Support the small-lot, mixed use pattern of Central Kaka`ako.
- Support TOD.

The Future Baseline Condition assumes that the project site will retain its current development parameters and land uses as allowed under the Mauka Area Rules (2011), Makai Area Rules (2005) and adopted Master Plans for Kamehameha Schools and Ward Center. All existing planning and implementation policies and existing development regulations would continue to guide development decisions for properties within the project area. This scenario would extend negotiated agreements in each of the Master planned areas and assumes that no new changes would occur to land use or transportation in the KCDD other than those already programmed as part of existing City or HCDA plan or proposed by other agencies. This scenario does not include direct coordination with the HART alignment or mitigations that will capture the value of this public investment. This scenario does not include Complete Streets planning policies.

The target year 2035 was determined by the availability of population forecasts developed by other agencies, including the State's Department of Business, Economic Development & Tourism ("DBEDT") and the City and County of Honolulu's Department of Planning and Permitting. The target year is not based upon market assumptions. No market analysis has been conducted. Rather, HCDA is responsible for putting rules in place to guide the redevelopment of the KCDD, irrespective of market conditions. Thus, for the purposes of this EIS, 2035 is identified as the target year for full build out in both the Future Baseline Condition and TOD Alternative A.

Kakaako Community Development District TOD Overlay Plan | FEIS Transportation Analysis
Hawaii Community Development Authority

TOD Alternative A (Draft TOD Overlay Plan)

For the purposes of this environmental impact statement, the TOD Alternative A is defined as the development activity envisioned in the Draft TOD Overlay Plan.

The primary purpose of the Draft TOD Overlay Plan is to coordinate future urban redevelopment with the provision of HART rapid transit so that residents, employees and visitors can take advantage of improved mobility choices. Land use policies in the Plan focus intensive mixed-use redevelopment into identified areas near to proposed HART transit stations.

The Draft TOD Overlay Plan also provides a comprehensive set of policies that aim to create a network of safe and comfortable streets with convenient access to HART stations. The Plan provides tools to introduce integrated transportation management, requirements for improved street connectivity, trip reduction (transportation demand management) measures, transit enhancements (feeder service, connectors and local bus enhancements), pedestrian and bike improvements, shared parking, and parking pricing. The Plan proposes no new development in the Makai District related to the proposed transit stations; however it envisions the integration of the Complete Streets concept throughout the Mauka and Makai Districts.

T he TOD Overlay Plan responds to the recent approval of the HART elevated rail system and the designation of three transit station locations within the KCDD. The coming introduction of rail transit - in parallel with community-driven interest in creating a city that is highly walkable, friendly and safe for cyclists – is an important reason for adopting the Draft TOD Overlay Plan. However the rail system is only an one outcome of a much broader movement to bring vitality to urban Honolulu, reflecting the values of the native Hawai`ian culture, particularly stewardship of the land and environment, preservation of the native culture, openness to the visiting world, and responsibility to local people and their prosperity.

The analysis of the TOD Alternative A tests the policy measures included in the Draft TOD Overlay Plan. This analysis includes a likely "best guess" scenario for the maximum development envelope given location and general economic factors. It explores the potential for proposed high rise building types and more intensive density allocations. A primary consideration of the TOD Overlay Alternative is how land use change might both respond to and support the HART rapid transit system as well as supplementary improvements for walking and cycling to create a pedestrian and transit friendly environment.

Potential Development under Future Baseline Condition & TOD Alternative A

Table 1 provides a comparison of potential land use buildout in the Year 2035 plan horizon year under the TOD Alternative A and Future Baseline Condition, as well as a comparison with Year 2010 land uses. As shown:

- Under the Future Baseline Condition, potential development in the KCDD would represent a net increase of approximately 18 million square feet of residential development and nine million square feet of non-residential space.
- The TOD Alternative A would potentially accommodate an additional 14 million square feet of residential development, as compared to the Future Baseline Condition. It would reduce the amount of non-residential space accommodated by about two million square feet as compared to the Future Baseline Condition.

Table 1 Land Use Comparison: Future Baseline Condition and TOD Alternative A

Land Use	Existing (2010)	Future Baseline (2035)	Future Baseline + TOD Alternative A (2035)
Residential	8,500,646 sq.ft.	28,562,707 sq.ft.	42,028,459 sq.ft
Non-residential	9,987,945 sq.ft.	19,033,286 sq.ft	16,771,407 sq.ft

EXISTING CONDITIONS

This section describes existing multi-model transportation conditions including:

- Existing trip generation and travel mode choice patterns
- Motor vehicle traffic
- Public transit service
- Bicycle circulation
- Pedestrian circulation

2.1 TRIP GENERATION & TRAVEL MODES

The regional trip generation model utilized by the Oahu Metropolitan Planning Organization (OMPO) accounts for a range of factors effecting transportation demand including land uses, number of households, and employment. Based on the regional distribution of land uses and transportation facilities, the model estimates the number of trips between origins (e.g. residences) and destinations (e.g. retail, employment). The model further estimates the portion of trips that occur via motor vehicle, transit, bicycling and walking.

Volume of daily trips (by all modes) is estimated by the OMPO model based on the existing mix of land uses within the traffic analysis zones (TAZ's) that include the KCDD.

- The TAZ's in the KCDD are currently developed with an estimated 11,887 residential units
- Non-residential uses within the TAZ's provide an estimated 36,219 jobs - 7,916 retail jobs and 28,303 non-retail jobs.

Based on the existing mix of land uses, the OMPO model[iv] estimates that 286,000 daily trips are made to, from, and within the study area:

- **Approximately 77 percent of daily trips are made via automobile** – including carpool trips. Based on estimated vehicle occupancy, the OMPO model estimates that existing land uses generate 184,797 daily vehicle trips. Since traffic studies frequently focus on traffic operations during the "peak hours" that coincide with morning and afternoon work-commute periods, the OMPO model also provides an estimate of peak-hour motor vehicle trip generation. It forecasts 13,822 vehicle trips generated during the AM Peak Hour and 9,249 vehicle trips generated during the PM Peak Hour.
- **Approximately seven percent of daily trips are made by transit** – an estimated 20,655 daily transit riders. The OMPO model does not provide an estimate of peak-hour transit ridership (instead, the peak-period transit ridership forecast is based on multi-hour morning and afternoon peaks).
- **Approximately 16 percent of daily trips are walk or bicycle trips** – an estimated 44,466 daily walk or bicycle trips.
- **Approximately 37 percent of daily trips are internal to the study area.** The portion of "internal trips" is a function of the mix of land uses.

Table 2 summarizes the estimate of existing daily trip generation derived from the OMPO Model.

Table 2 Trip Generation by Existing Land Uses (OMPO Model Estimate)

	Vehicle Trips			Transit Trips	Walk/Bike Trips
	AM Peak Hour	PM Peak Hour	Daily	Daily	Daily
Existing Conditions (2015 Base Year)	13,822	9,249	184,797	20,655	44,466

Work Trips by Existing Residents[v]

Census data on the journey to work is frequently used as a source for mode share data, because it is one of the few universally available data sets that permits "apples to apples" comparisons. Figure 5 provides a summary of travel mode data for "journey to work" trips by area residents, based on data provided for Census Tract 37, Census Tract 38, and Census Tract 39 (thus comprising an area slightly larger than the project area).

As shown on Table 3, over 16 percent of area residents walk to work, while the rate of bicycling to work (3.6 percent) is nearly as high as the rate of transit ridership to work (3.8 percent).

Figure 3 Kaka`ako Census tracts

Census tracts 37, 38 & 39

Table 3 Existing Travel Modes: Work Trips by Existing Residents

Workers 16 years and over	Census Commute Mode Share
Car, truck, or van	70.6%
Drove alone	58.1%
Carpooled	12.5%
In 2-person carpool	10.4%
In 3-person carpool	0.0%
In 4-or-more person carpool	2.0%
Public transportation (excluding taxicab)	3.8%
Walked	16.2%
Bicycle	3.6%
Taxicab, motorcycle, or other means	2.4%
Worked at home	3.4%

Hawaii Community Development Authority

Mode Share Comparison

Table 4 provides a comparison of travel mode shares for total daily trips, based on the OMPO model, and work trips for Kaka`ako area residents (based on the US Census data summarized above).

- Rates of walking and bicycling to work are high for work trips by Kaka`ako residents – nearly 20 percent walk or bicycle to work – reflecting the proximity of Kaka`ako residences with nearby jobs, within KCDD and in adjacent employment and commercial areas including downtown and the Ala Moana Center.
- The overall rate of walking and bicycling to and from Kaka`ako (Total Daily Trips based on the OMPO model), which includes non-work trips by residents and non-residents, is estimated at under 15.5 percent.
- The rate of transit use is over 7 percent for all trips to and from Kaka`ako, compared to less than 4 percent for Kaka`ako residents. –This difference reflects residents' greater propensity for walking and bicycling to nearby jobs as noted above.
- Note that the data comparison shown on Table 4 is not strictly an "apples to apples" comparison, since the percentage of workers that "work at home" is also included in the U.S. Census data.

Table 4 Existing Travel Mode Comparison

	Total Daily Trips to/from Kaka'ako (Base Year 2015 OMPO Model)	Work Trips Only – Kaka`ako Residents (US Census Journey-to-Work Data)
Motor Vehicle (including motorcycle & taxi)	77.3%	73.0%
Walk + Bicycle	15.5%	19.8%
Public Transit	7.2%	3.8%
Work at Home	N/A	3.4%

2.2 STREET NETWORK

The major Ewa -Diamond Head (east-west) connections are: Ala Moana Boulevard, and Kapiolani Boulevard. The secondary connection is Queen Street.

- **Ala Moana Boulevard** (State Route 92) is a 6-lane east-west arterial street through the southern portion of the KCDD that connects to the west with Nimitz Highway to the west, and connects Downtown Honolulu, Kaka`ako, Ala Moana Center and areas to the east near Waikiki. Pedestrian crossing distances are over 70 feet at most locations. No bicycle lanes are provided.
- **Kapiolani Boulevard** is a 6-lane east-west arterial street through the northern portion of the KCDD that connects areas to the east near Waikiki with Kaka`ako, and Downtown Honolulu via King Street. Pedestrian crossing distances are approximately 64 feet at most locations. No bicycle lanes are provided.
- **Queen Street** is a 2-lane collector street between Kamakee and Cooke Streets, widening to 4 lanes west of Cooke Street to downtown. Pedestrian crossing distances are generally 44 feet or less. Sidewalks are missing on some segments. No bicycle lanes are provided.

The major Mauka - Makai (north-south) connections are: Ward Avenue, Piikoi Street, and Punchbowl Street. Secondary connections are: South Street, Cooke Street, and Kamakee Street.

- **South Street** and **Punchbowl Street** are north-south collector streets at the western edge of the study area that connect Ala Moana Boulevard and King Street. Crossing distances vary, generally between 54 to 64 feet. No bicycle lanes are provided.
- **Cooke Street** is a 4-lane street that extends from south of Ala Moana Boulevard to King Street. Crossing distances are approximately 44 feet at most locations. No bicycle lanes are provided.
- **Ward Avenue** is a 4-lane north-south collector that extends from the south of Ala Moana Boulevard to the north of King Street. Crossing distances are approximately 64 feet at most locations. No bicycle lanes are provided.
- **Kamakee Street** is a 4-lane north-south street that connects Ala Moana Boulevard and Kapiolani Boulevard, to the east of Ward Avenue. Crossing distances vary between approximately 44 to 58 feet. No bicycle lanes are provided.
- **Piikoi Street** is a north-south arterial street at the eastern edge of the study area that connects with Ala Moana Boulevard to the east of the KCDD, adjacent to the Ala Moana Center. North of Kapiolani Street: Piikoi serves one-way northbound motor vehicle traffic, while southbound traffic travels one block west on Pensacola Street. Crossing distances vary, generally between 60 to 64 feet. No bicycle lanes are provided.

A map of the roadway network serving the area is shown on Figure 4, based on the street typologies described in the *Mauka Area Thoroughfare Plan*. Estimated daily traffic volumes on key corridors are shown on Figure 5.

A description of right-of-way widths within the study area is provided on Table 5.

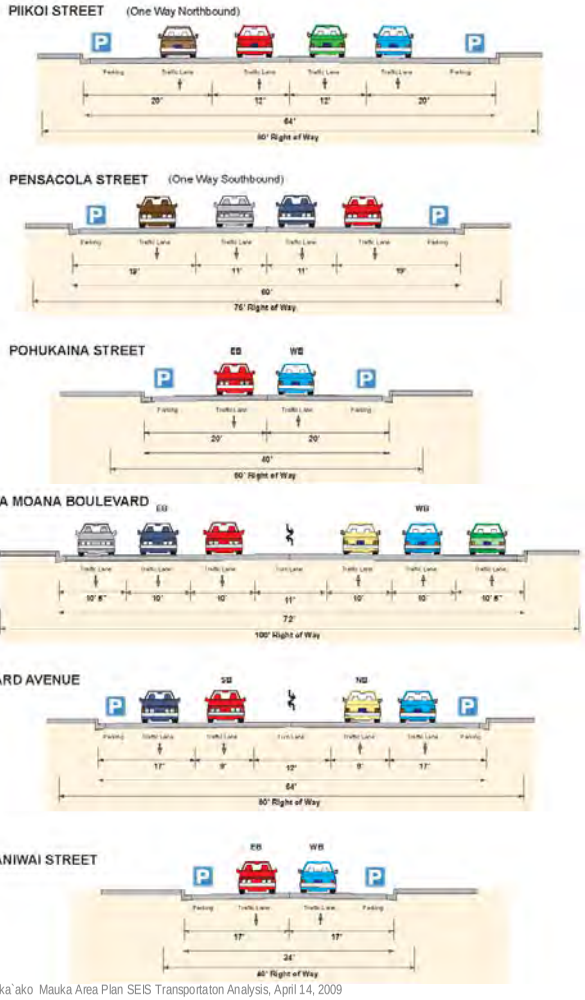
Figure 5 Key Traffic Corridors within KCDD

Existing Street Dimensions



Street types and right-of-way widths are summarized on Table 5. Cross-section drawings showing existing lane allocations and travel-way widths are provided for each of the primary streets serving the study area on Figures 6 to 8. On-street parking restrictions by street frontage are summarized on shown on Figure 9.

Table 5 Street Types & Right-of-way Widths

Street Name	Road Type	Right-of-Way Width (feet)
King	Avenue	90'
Kapiolani	Boulevard	100'
Queen	Street	Varies, 50'-60'
Queen Extension/ Waimanu	Street	100'
Halekauwila	Street	60'
Pohukaina	Promenade Street	60'
Auahi (Ward to Queen Lane)	Promenade Street	60'
Auahi (Ahui Ext. to South)	Promenade Street	60'
Ala Moana Boulevard	Promenade Boulevard	100'
Waimanu (Dreier to Kamakee)	Service Street	40'
Kawaiahao	Street	50'
Ilaniwai	Service Street	40'
Kona	Service Street	40'
Hopaka	Alley	19'
Punchbowl	Promenade Avenue	70'
South	Avenue	Varies, 66'-80'
Cooke	Promenade Street	60'
Ward Avenue	Promenade Avenue	80'
Kamakee	Promenade Street	76'
Piikoi	Avenue	80'
Pensacola	Avenue	76'
Keawe	Street	50'
Coral	Service Street	40'
Emily	Service Street	40'
Curtis	Service Street	40'
Dreier	Service Street	40'
Koula (Ala Moana to Halekauwila)	Service Street	40'
Ahui & Ahui, Extension to Ala Moana	Street	50'

2.3 TRAFFIC OPERATIONS

Study Intersections

Based on the criteria described in Section 1.6, the significance of impacts resulting from the TOD Alternative A is based on the effect on key intersections. The majority of study intersections are located on the key east/west and north/south transportation corridors that provide access to KCDD, downtown, and Ala Moana Center.

Figure 10 shows the location of each study intersection. HCDA selected the following 48 study intersections for this analysis:

1. Kapiolani Boulevard/South Street/King Street
2. Kapiolani Boulevard/Ward Avenue
3. Kapiolani Boulevard/Kamakee Street
4. Kapiolani Boulevard/Pensacola Street
5. Kapiolani Boulevard/Piikoi Street
6. Ala Moana Boulevard/South Street
7. Ala Moana Boulevard/Keawe Street
8. Ala Moana Boulevard/Coral Street
9. Ala Moana Boulevard/Cooke Street
10. Ala Moana Boulevard/Ward Avenue
11. Ala Moana Boulevard/Kewalo Basin
12. Ala Moana Boulevard/Kamakee Street
13. Ala Moana Boulevard/Queen Street
14. Ala Moana Boulevard/Piikoi Street
15. Ward Avenue/Auahi Street
16. Ward Avenue/Halekauwila Street
17. Ward Avenue/Queen Street
18. Piikoi Street/Ala Moana Shopping Center/Hawaiki Tower
19. Piikoi Street/Waimanu Street
20. Piikoi Street/Kona Street
21. Pensacola Street/Waimanu Street
22. Kamakee Street/Queen Street
23. Kamakee Street/Auahi Street
24. Auahi Street/Pedestrian Crossing (Ward Entertainment Center)
25. Auahi Street/Pedestrian Crossing (Ward Warehouse/Farmers Market)

Figure 10 Study Intersection Map

Existing Traffic Volumes

Peak-period intersection volume counts[vi] were conducted during the week of January 15, 2013 at each study intersection:

- Travel counts included motor vehicle movements and pedestrian crossings at each study intersection. Count sheets from each location are provided in Appendix A.
- Morning counts were conducted from 7:00 AM to 9:00 AM. Afternoon counts were conducted from 4:00 to 6:00 PM. Based on those 2-hour counts: the "peak hour" was determined at each study intersection based on the highest consecutive 60-minute volume.

Peak-hour motor vehicle volumes at each study intersection are shown on Figures 11 to 13.

Figure 11 Existing Peak Hour Motor Vehicle Volumes

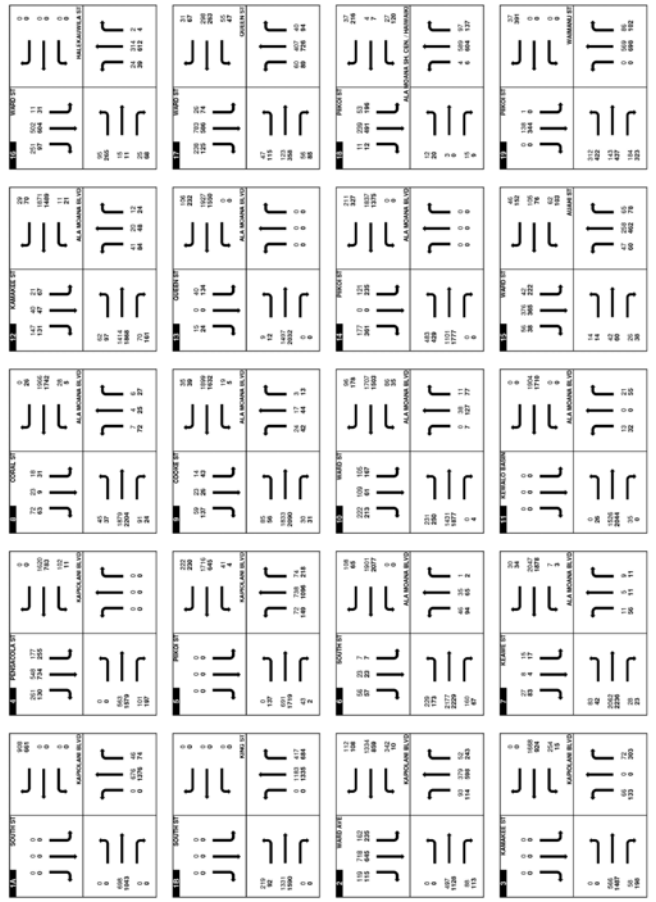

Figure 12 Existing Peak Hour Motor Vehicle Volumes

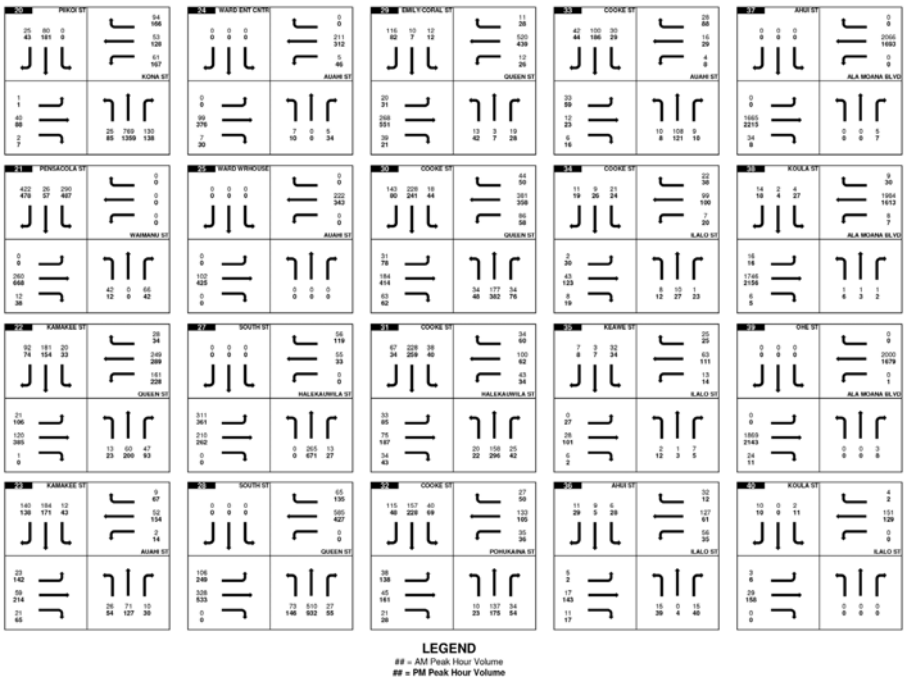

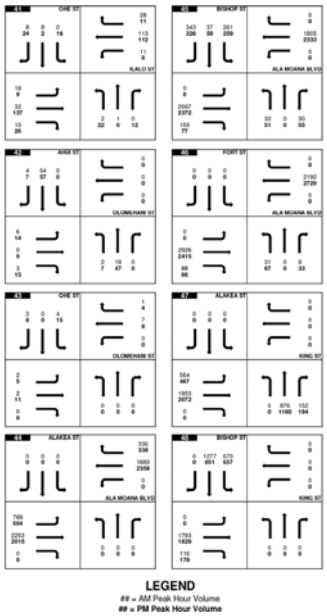

Figure 13 Existing Peak Hour Motor Vehicle Volumes

Existing Traffic Operations

Traffic operations are typically evaluated based on Level of Service (LOS) standards described in the Highway Capacity Manual (HCM). LOS is a qualitative description of traffic flow based on such factors as speed, travel time, delay, and freedom to maneuver. Six levels are defined from LOS A, which represents free flowing operating conditions, to LOS F, which represents the most congested conditions. LOS E represents "at-capacity" operations. When traffic volumes exceed the capacity, stop-and-go conditions result, and operations are designated as LOS F.

Table 7 summarizes the LOS definitions for each rating (A though F) for both signalized and stop-sign controlled intersections.

A key distinction when determining LOS pertains to the assessment of side-street stop-signed controlled intersections:

- At signalized intersections, and at "all-way stop-sign controlled intersections", the methodology for calculating LOS is based on average motor vehicle delay for all approaches.
- The LOS methodology differs slightly for side-street stop-sign controlled intersections. For these intersections, LOS is based on average delay to the side-street (approaching the stop-sign). This study includes several side-street stop-sign controlled intersections, including the stop-sign controlled to Ala Moana Boulevard at Ahui Street and Kaula Street.

Operational observations and field assessments were conducted to calibrate the traffic operations analysis methodology. Traffic signal-timing plans were provided for use in the analysis. Analysis of traffic operations and corridor travel time was conducted utilizing SYNCHRO 8 analysis software and SimTraffic microsimulation. Travel-time by automobile was field-checked based on multiple runs via automobile during the AM and PM Peak Hours. Existing travel speeds are presented in Table 6.

Table 6 Estimated Net Travel Speeds - Existing

Street	Direction	AM Peak Hour	PM Peak Hour
Ala Moana	Eastbound (Piikoi to Fort)	14 mph	10 mph
	Westbound (Fort to Piikoi)	10 mph	14 mph
Queen	Eastbound (South St to Kamakee)	16 mph	15 mph
	Westbound (Kamakee to South St)	14 mph	12 mph
Ward	Northbound (Ala Moana to Kapiolani)	11 mph	10 mph
	Southbound (Kapiolani to Ala Moana)	14 mph	14 mph

Table 7 Intersection Level of Service Definitions

LOS	Flow Type	Operational Characteristics	Intersection Control Delay (seconds/vehicle)	
			Signal Control	2-Way-Stop or All-Way Stop Control
A	Stable Flow	Free-flow conditions with negligible to minimal delays. Excellent progression with most vehicles arriving during the green phase and not having to stop at all. Nearly all drivers find freedom of operation.	< 10	0 – 10
B	Stable Flow	Good progression with slight delays. Short cycle-lengths typical. Relatively more vehicles stop than under LOS A. Vehicle platoons are formed. Drivers begin to feel somewhat restricted within groups of vehicles.	> 10 – 20	> 10 – 15
C	Stable Flow	Relatively higher delays resulting from fair progression and/or longer cycle lengths. Individual cycle failures may begin to appear. The number of vehicles stopping is significant, although many still pass through without stopping. Most drivers feel somewhat restricted.	> 20 – 35	> 15 – 25
D	Approaching Unstable Flow	Somewhat congested conditions. Longer but tolerable delays may result from unfavorable progression, long cycle lengths, and/or high volume-to-capacity ratios. Many vehicles are stopped. Individual cycle failures may be noticeable. Drivers feel restricted during short periods due to temporary back-ups.	> 35 – 55	> 25 – 35
E	Unstable Flow	Congested conditions. Significant delays result from poor progression, long cycle lengths, and high volume-to-capacity ratios. Individual cycle failures occur frequently. There are typically long queues of vehicles waiting upstream of the intersection. Driver maneuverability is very restricted.	> 55 – 80	> 35 – 50
F	Forced Flow	Jammed or grid-lock type operating conditions. Generally considered to be unacceptable for most drivers. Zero or very poor progression, with over-saturation or high volume-to-capacity ratios. Several individual cycle failures occur. Queue spillovers from other locations restrict or prevent movement.	> 80	> 50

Source: Highway Capacity Manual (HCM) 2010

Table 8 summarizes Existing AM & PM Peak Hour LOS at each study intersection, based on the Existing Conditions analysis steps described above. As shown:

- The following intersections operate at LOS E during the AM or PM Peak Hour, indicating congested conditions:

  - Ala Moana & South/Forest
  - Ala Moana & Ward
  - Bishop & King
- During the peak periods, the peak-direction traffic flow in the "peak direction" (westbound AM, eastbound PM) results in queues that affect downstream intersections. Lengthy signal cycle lengths on the major east/west arterial corridors contribute added delay to motorists, pedestrians and cyclists, during peak as well as off-peak hours. The east/west cycles vary from 100 to 140 seconds. Such cycles are much longer in duration than found in most central-city or downtown areas, and may conflict with goals aiming at creating a walkable, multi-modal environment.

Table 8 Peak Hour Intersection Level of Service (Existing Conditions)

Intersection Number	Street Names	Control Type	AM LOS (Delay)	PM LOS (Delay)
1a	South at Kapiolani	Signalized	B (19)	C (24)

2.4 PUBLIC TRANSIT

Existing Transit Service

The City and County of Honolulu is served by The Bus, one of the most highly used public bus systems of any city in the nation on a per capita basis. TheBus is operated by Oahu Transit Services (OTS) and provides fixed-route public transit and paratransit service in the Mauka Area, Honolulu, and throughout the island of O`ahu. TheBus operates a "hub-and-spoke" network, with the majority of services centralized along major corridors and serving major destinations. Within the Mauka Area, most lines run along major corridors such as King Street, Kapiolani Boulevard, and Ala Moana Boulevard. Existing transit service in the Mauka Area in the AM and PM peak periods is summarized in Table 9 below and is mapped in Figure 14.

Major trunk lines such as the 1 / 1L and 2 / 13 provide high-frequency service all day, with the remainder operating at lower and sometimes irregular frequencies. Feeder lines connect various neighborhoods within Honolulu to major destinations or transfer points. Peak express buses run a limited number of runs in the peak period in the peak direction, connecting various parts of O`ahu with Downtown Honolulu and the Mauka Area. TheBus also operates four rapid bus lines through the Mauka Area: CityExpress A, CityExpress B, CountryExpress C, and CountryExpress E. TheBus service is complemented by ferry service operated as TheBoat, which runs between the Aloha Tower in Downtown and Kalaeloa on the west side of Oahu. Connecting bus services operate as "F-series" lines at both ferry terminals.

Figure 14 Existing Transit Service Map

Existing Transit Ridership & Capacity

A screenline analysis was used to evaluate transit operations. A screenline is a theoretical grouping of transit lines that serve an identifiable corridor or area, chosen such that it passes these lines either at or near their maximum load point (MLP). The MLP is defined as the point along a particular route at which passenger loading on the transit vehicle is the highest. For example, for a peak express line that serves Downtown Honolulu, the MLP could be considered the point at which the bus leaves Downtown and enters the freeway, as the bus is most crowded after all the passengers who will ride have boarded. After it exits the freeway and passengers begin alighting, the bus only gets less and less crowded.

Once the relevant transit lines are grouped into screenlines, the ridership and capacity for each screenline are combined to obtain a capacity utilization ratio—the ratio of ridership to capacity. A screenline operating at a high capacity utilization indicates that transit vehicles operating on lines grouped in that screenline generally operate with high loads relative to vehicle capacity. For the purpose of this study, a capacity utilization of more than 80 percent is considered a "high load" and would require mitigations.

To obtain screenline ridership and capacity, the ridership and capacity for each individual screenline are summed together. For the purposes of this study, ridership information and capacity numbers are taken from the 2009 EIS. Capacity in the 2009 EIS was calculated based on vehicle size and capacity (both seated passengers and standees) and line frequency.

The screenline analysis assumes that the AM peak direction travels into the Mauka Area in the and out of the Mauka Area in the PM peak period. **Error! Reference source not found.** provides an overview of ridership, capacity, capacity utilization across the screenlines in the AM and PM peak directions. Figure 15 and Figure 16 illustrate this analysis graphically.

Table 10 Existing Transit Capacity Utilization

Screenline	Existing Conditions		
	Ridership	Capacity	Capacity Utilization
AM Beak Hour - Inbound			
East	4,635	10,500	44%
West	2,943	6,720	44%
North	351	480	73%
Total	7,929	17,700	45%
PM Peak Hour - Outbound			
East	2,915	6,300	46%
West	4,645	10,590	44%
North	440	660	67%

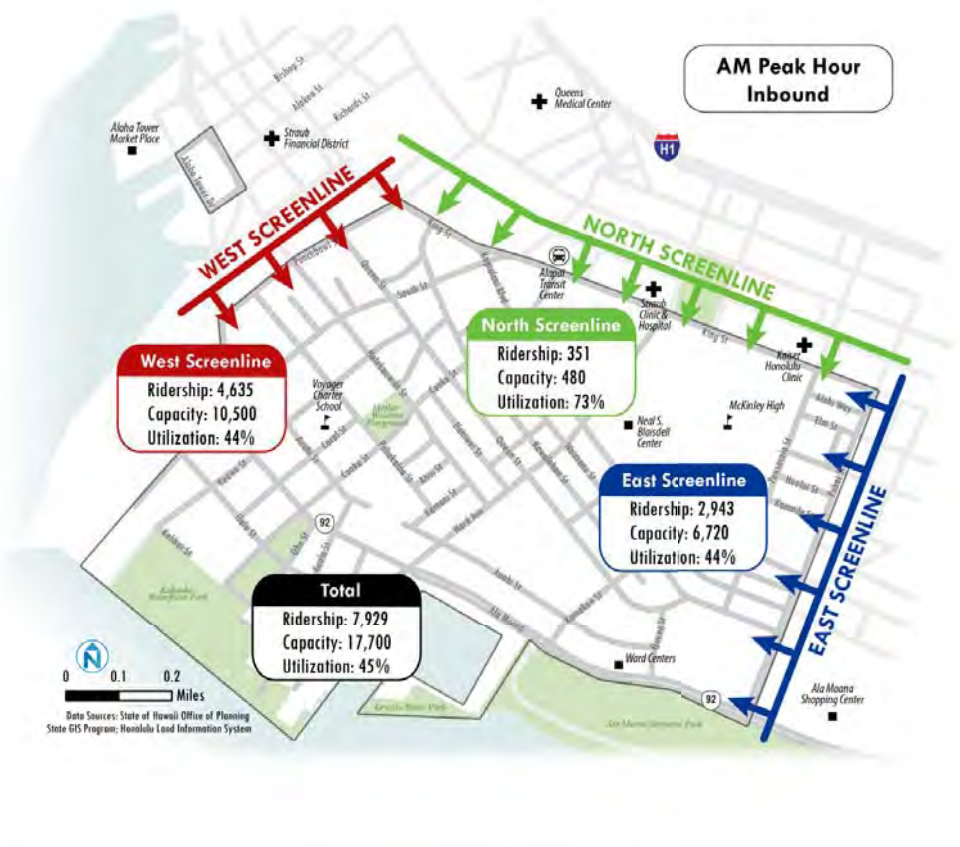

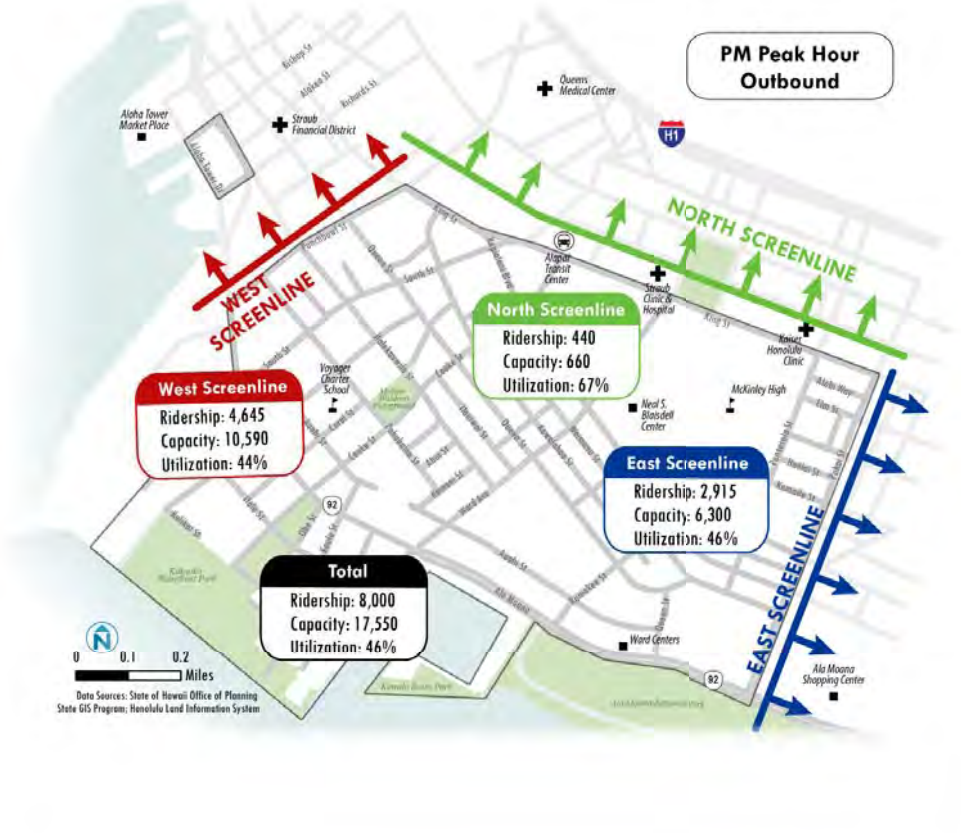

Figure 16 Existing Transit Capacity Utilization PM Peak Hour

2.5 BICYCLE CIRCULATION

Existing Bicycle Routes

Bicyclists traveling to and through the Kaka`ako Community Development District generally must share travel lanes with automobiles to access destinations because there are limited designated bicycle facilities. The Aloha Tower Special District is not served by existing bicycle facilities. The most direct routes for bicycle travel—including King Street, Kapiolani Boulevard, and Ala Moana Boulevard—are not popular or comfortable cycling routes due to heavy vehicle volumes, high off-peak travel speeds, and the absence of dedicated bicycle facilities. As shown in Figure 17, there are only three short bikeway segments within the project area, including:

- **Kaka`ako Waterfront Park multi-use path:** A bicycle and pedestrian only path facility (Class I) that provides fully separate from the nearest parallel roadway (Ala Moana Boulevard). The path runs from Kakaako Waterfront Park in the Makai Area east through Kewalo Basin and Ala Moana Park. Travel to and from neighborhoods and destinations Diamond Head of the project area can be made by bicycle on this facility; however, a variety of gaps make this connection challenging and exposes cyclists to various conflicts with turning automobiles.
- **Keawe Street southbound bike lane:** This one-way dedicated striped and signed bicycle facility (Class II) spans from Ilalo Street southbound to the Keawe Street end at Kaka`ako Waterfront Park. The bike lane is proximate, but does not connect with the Kaka`ako Waterfront Park multi-use path due to a chain link fence barrier. This is the only existing bike lane in the project area.
- **Queen Street/Waimanu Street bike route:** This unmarked partially signed bicycle route (Class III) connects cyclists from Kamakee Street to Piikoi Street. This facility is overlaid on a 4-lane configuration (two lanes in each direction from Pensacola Street to Kamakee Street; four lanes in one direction from Pensacola Street to Piikoi Street). No pavement markings—like shared lane markings (also known as sharrows)—are provided for safe riding location or wayfinding. The only signage indicating the bicycle route designation is provided on the Waimanu Street segment from Pensacola Street to Piikoi Street.

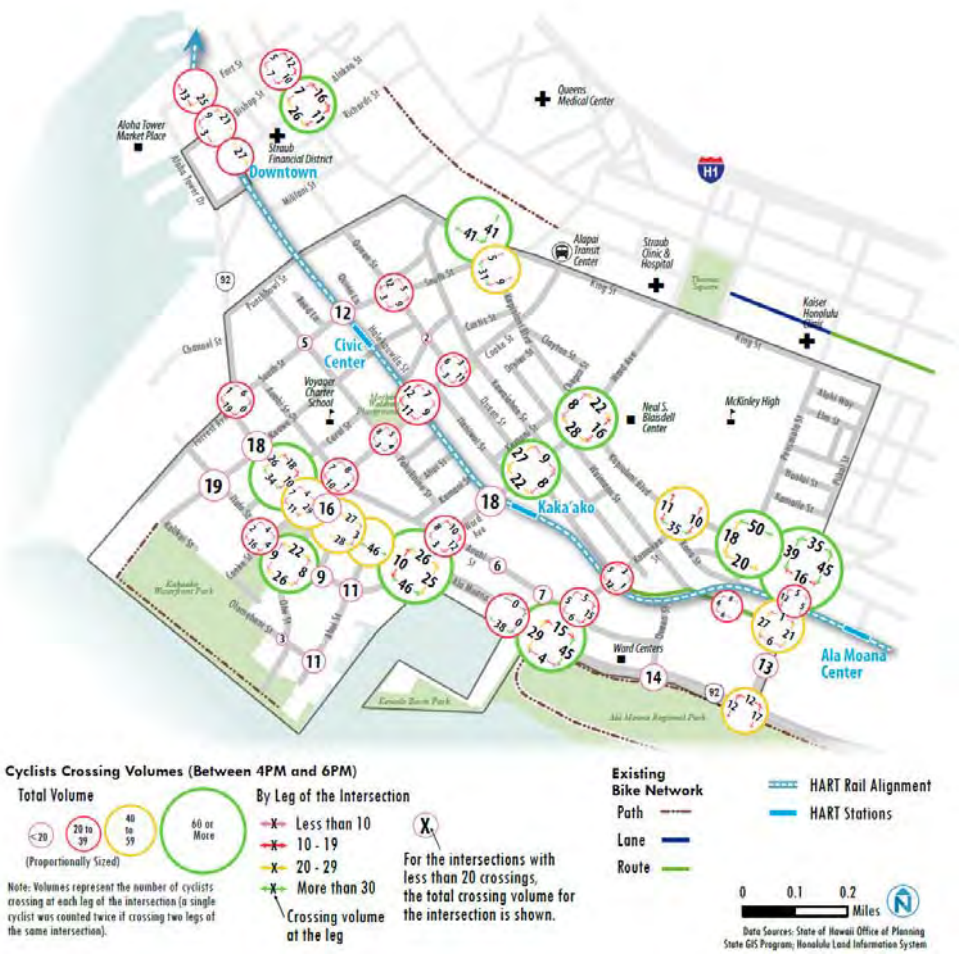
Other designated facilities in the vicinity of the project area that provide access to Kaka`ako include:

- Ala Moana Regional Park multi-use path—a Class I bicycle facility connecting cyclists to Ala Moana Center and Waikiki.
- Young Street bike lane and bike route—a key east-west bicycle street with a mixture of Class II and III facilities connecting bicyclists between the Kaka`ako and McCully-Mo`ili`ili neighborhoods.
- Capital Historic District/Alapai Transit Center multi-use path linkage—a Class I bicycle facility from Kealamakai Street to Richards Street connecting cyclists to the Alapai Transit Center, the Hawai`i Capital Historic District, and Downtown.
- Hotel Street bike route—a shared bus and bike only street from Richards Street to River Street at the edge of Downtown Honolulu.

In addition, several low speed, low volume internal streets provide relatively comfortable and direct shared roadway bicycle connections *within* the project area. This includes Ilalo Street, Keawe Street, Pohukaina Street, Waimanu Street, and Kawaiahao Street. Although these streets provide comfortable shared roadway operating environment for bicycles, nearly all of the connections are bookended by a major arterial crossing barrier, a street end (i.e., cul-de-sac), or off-set intersection that requires travel on a short high speed, high volume segment. It should be noted that only one viable north-south shared roadway connection is available (Cooke Street), which requires bicycles entering or exiting the district to use one of the higher speed and volume streets.

Existing Bicycle Volumes

As part of the transportation analysis, bicycle counts were collected in the PM peak travel period. The most heavily travelled bicycle corridors during PM peak includes Kapiolani Boulevard (up to 70 east-west crossings), Ala Moana Boulevard (up to 72 east-west crossings), Piikoi Street (up to north-south 84 crossings), Kamakee Avenue (up to 74 north-south crossings), and Ward Avenue (up to 35 north-south crossings). While bicycle travel along high traffic corridors and freeway access routes for automobiles is not preferred by most bicyclists, there are limited routing options for cyclists that seek direct travel and limited delay at unsignalized crossings.



Bicyclists observed during the bicycle count typically used the right-most travel lane adjacent to curbside parking (or adjacent to the curb where parking is not permitted), or rode on the sidewalks.

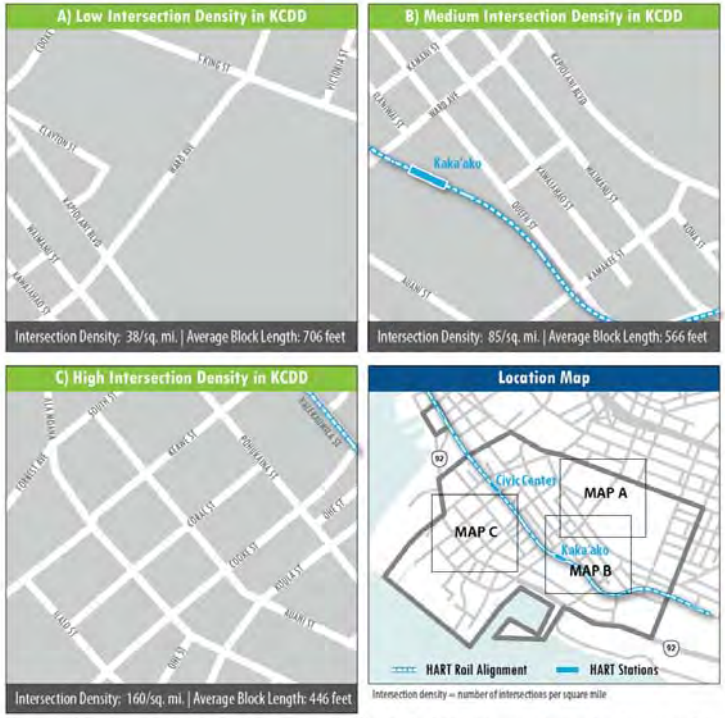
2.6 PEDESTRIAN CIRCULATION

Existing Pedestrian Facilities

Current pedestrian conditions of the proposed project area are described in this section. Existing pedestrian conditions vary in quality and facility availability (sidewalks, crossings, amenities, etc.). Many streets in Central Kaka`ako, including Queen Street and Waimanu Street, exhibit curbless industrial character. These streets lack curbs and sidewalks, forcing pedestrians to walk in the street without the necessary design features to ensure pedestrian comfort and safety. Other streets, like those bounding the Ward Centers, are highly oriented towards pedestrians.

This variance is due, in part, to the diversity of land uses in the project area (particularly the industrial land use character in Central Kaka`ako) and the relative level of pedestrian orientation along and across each street. Pedestrian orientation is based on a variety of factors, including, but not limited to, sidewalk coverage and width, pedestrian-supportive amenities (e.g., shade tree canopy, benches, landscaping, etc.), walk distances, availability of marked crossings and short crossing distances, pedestrian delay acceptable for urban conditions, and traffic conditions (distance from adjacent traffic, traffic speed and volumes, etc). Only a few streets in Kaka`ako have the qualities typical of a highly pedestrian oriented environment: these pedestrian-friendly streets include portions of Ilalo Street, Kapiolani Boulevard, Ward Avenue (immediately makai of Ala Moana Boulevard), Auahi Street, Kamakee Street, and Piikoi Street. In summary, pedestrian facilities in Kaka`ako can be characterized as follows:

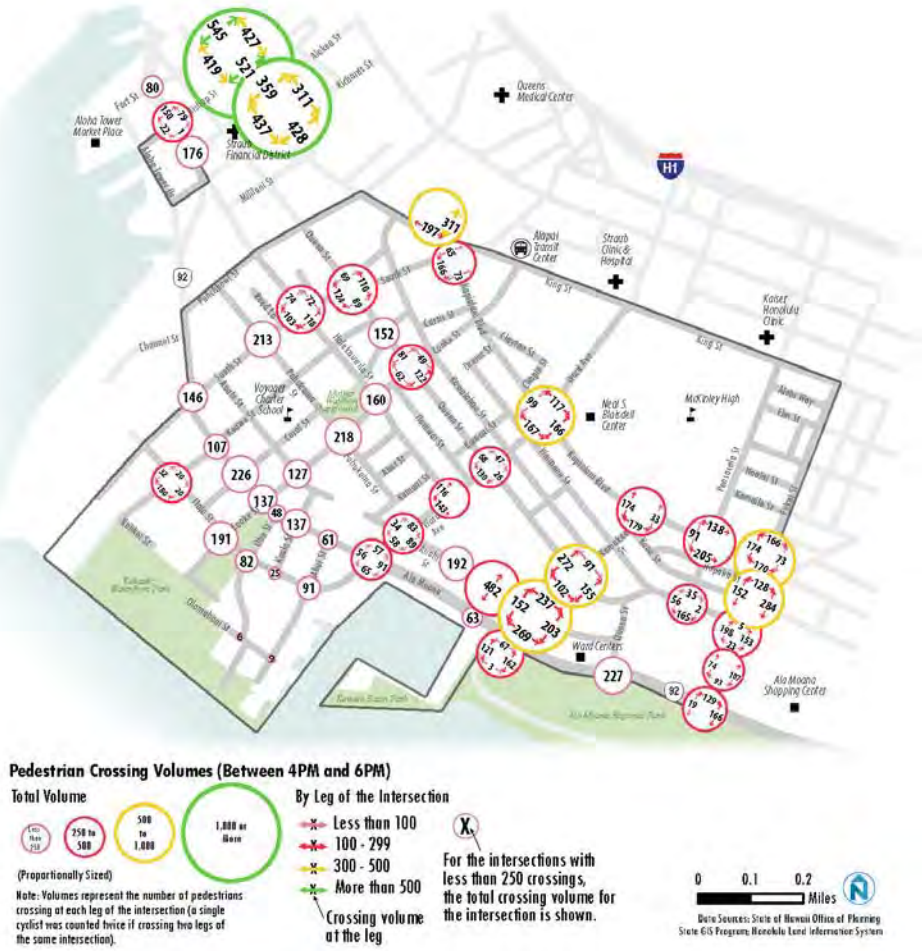


- **Street Frontages.** Activating street frontages with pedestrian-oriented land uses and inviting pedestrian and bicycle environments helps to encourage walking to work, retail, and other commercial destinations. These active environments can be found in small pockets of Auahi Street and Cooke Street. Without the appropriate zoning regulations to ensure active street environments, very large retail establishments (100,000 square feet or larger) like Ward Centers and Ala Moana Center are typically antithetical to this pedestrian orientation factor.
- **Sidewalk coverage and width.** For the purposes of this study, existing sidewalk in the Mauka Area is defined as either obstructed (effective width less than 4' feet) or unobstructed (effective width greater than or equal to 4'). Sidewalk widths in the project area range between spacious (Kapiolani = 17') and very constrained (makai side of Ala Moana = 3-4'). Most commercial streets (e.g., Cooke, Ward, Pensacola) have 10-foot sidewalks to support pedestrian activity, while many residential serving streets offer 4-6' sidewalks. As illustrated in Figure 19, most streets outside of Central Kaka`ako and the Makai area have sidewalks on both sides of the street. The industrial character of many internal streets require pedestrians to share space with cars and parking storage. Some streets like Ala Moana Boulevard and King Street have obstructions like utilities, landscaping, and transit facilities that may impact people using mobility devices.
- **Pedestrian-supportive amenities.** Some streets provide generous pedestrian amenities like shade trees, benches, landscaped buffers, and planters that enhance the pedestrian experience and attract pedestrians. Kapiolani Boulevard, Ilalo Street, and parts of Auahi Street, Waimanu Street and Piikoi Street are model examples of high amenity streets.

Figure 19 Existing Sidewalk Network

- **Block sizes and walking distances.** Block size, which defines intersection density, is an enormously important factor that influences the accessibility and walkability of an area. Smaller block sizes decrease walking distances and, coupled with good urban design, tend to increase walkability and improve the pedestrian experience. Limited mid-block crossing opportunities either require longer walking distances to destinations (depending on routing and trip origin), or could encourage risky walking behavior, such as jaywalking and ignoring traffic control devices. Providing throughways or internal accessways within a larger development site breaks up the massive scale of large blocks and improves circulation through and around the site. This feature is only available in a few locations.

Figure 20 Existing Block Length Examples



Note: The following analysis only calculates intersection density for full street connections, not pedestrian and service alleys.

- **Crossings.** There are limited marked crossings throughout the project area. Most marked crossings are striped at signalized intersections, most of which are marked on all four legs. There are a variety of crossing conditions that create long crossing distances for pedestrians including wide arterial curb-to-curb widths (4 lanes and over), skewed intersections (see the King/Kapiolani and Ala Moana/Ward intersections), intersection legs closed to pedestrians, large curb radii at intersection corners, and a general lack of curb extensions. Many of these conditions are prevalent throughout the project area.
- **Pedestrian delay.** Pedestrians experience long delays while crossing some arterials. In highly urbanized areas, pedestrian delay ranging from 70-80 second cycles is generally viewed as acceptable. Pedestrians crossing (north-south) at Ala Moana Boulevard commonly experience 140 second cycles, while street pushes through AM and PM peak auto volumes.

Pedestrian Volumes

Figure 21 displays PM peak period pedestrian crossings throughout the project area. Pedestrian traffic is low in much of the project area, particularly compared to Downtown or Waikiki; many more people travel on foot on the western edge of the district adjacent to downtown and the government office areas. The highest level of pedestrian activity occurs near major transit stops on Ward Avenue and Kapiolani Boulevard and in areas where there are higher concentrations of retail and services. Bishop Street, Richards Street, Kamakee Street, Piikoi Street, Ward Avenue, and Kapiolani Boulevard are corridors that produce the highest number of PM peak period crossings in the project area.

Figure 21 Existing Pedestrian Crossing Volumes at Intersections (2-hour PM Peak)

FUTURE BASELINE CONDITION

This section describes conditions under the Future Baseline Condition. It describes Forecast Year 2035 trip generation and travel mode choice patterns, as well as motor vehicle, public transit, bicycle and pedestrian circulation conditions for this alternative. .

3.1 TRIP GENERATION & TRAVEL MODES

Travel Demand Forecast – Year 2035 Baseline (Future Baseline Condition)

The OMPO model was utilized to provide a forecast of trip generation based on Future Baseline Condition (Year 2035 Baseline) land uses. The net change to trip generation was derived based on existing land uses under the OMPO Model Year 2015 Baseline scenario. Table 11 provides a summary of the travel demand forecast. As shown:

- Total trips by all modes to, from, and within the study area will approximately double as a result of expected development under the Future Baseline Condition.
- Rates of walking and bicycling – as a portion of total trips – will increase from 15 to 20 percent, while rates of driving – as a portion of total trips – will decrease from 77 to 71 percent.
- The portion of daily trips internal to the study area will increase from approximately one-third to over one-half of daily trips.

Table 11 Future Baseline Condition – Travel Mode Comparison (Year 2035)

	Existing Conditions (Model Base Year)	Future Baseline Condition (Model Year 2035 Baseline)
Households	11,867	38,221
Retail Employment	7,916	16,840
Non-Retail Employment	28,303	44,739
Daily Trips (all modes)	286,878	569,295
Transit Mode Share	7.2%	8.7%
Walk + Bike Mode Share	15.5%	20.1%
Automobile Mode Share	77.3%	71.3%
Internal Capture (portion of daily trips with origins & destinations within the study area)	36.7%	51.3%

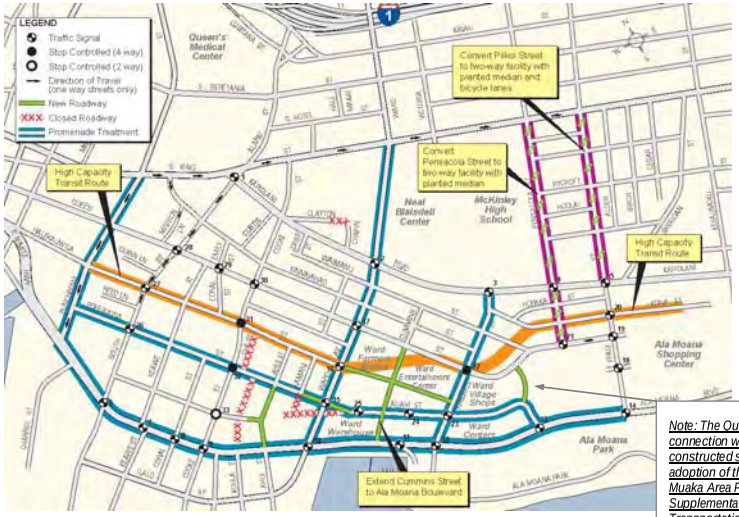
Trip Generation – Year 2035 Baseline (Future Baseline Condition)

Table 12 provides a comparison of motor vehicle, transit and walk/bike trips generated by land uses within the Plan Area, based on the regional model, under Existing and Year 2035 Future Baseline conditions. As shown:

- Motor vehicle trips will increase by approximately 80 percent over existing conditions – from approximately 185,000 daily under Existing Conditions to approximately 338,000 daily in Year 2035 under the Future Baseline Condition.
- Transit trips will more than double – from approximately 20,000 daily transit trips under Existing Conditions, to nearly 50,000 daily trips to/from the study area in Year 2035.
- Bicycle and walking trips will nearly triple – from approximately 44,000 under Existing Conditions to over 114,000 in Year 2035.

Table 12 Future Baseline Condition – Trip Generation Comparison (Year 2035)

	Vehicle Trips			Transit Trips	Walk/Bike Trips
	AM Peak Hour	PM Peak Hour	Daily	Daily	Daily
Existing Conditions	13,822	9,249	184,797	20,655	44,466
Year 2035 Baseline (Future Baseline Condition)	25,380	28,313	338,256	49,528	114,428
Net Trip Generation (Future Baseline Condition)	*11,558*	*19,064*	*153,459*	*28,873*	*69,962*



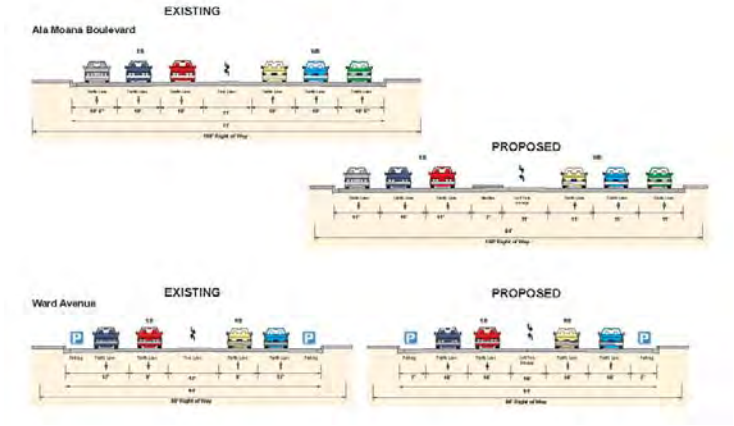
3.2 FUTURE BASELINE ROADWAY NETWORK

Analysis of the Future Baseline Condition is based on an assumed future roadway network, this network includes some *but not all* of the roadway network changes that were analyzed as part of the 2009 SEIS (displayed in Figure 22). Figures 23-27 illustrate the changes to key roadways that are anticipated under the Future Baseline Condition. They are as follows:

- Widening of Ala Moana Boulevard from 72 feet (under Existing Conditions) to 84 feet (under Year 2035 conditions), in order to provide additional left-turn capacity.
- Restriping of Ward Avenue to modify lane widths (but with no change to number of lanes or curb-to-curb width).
- The proposed 2-way conversion of Piikoi and Pensacola (as shown on Figure 24) is not included in the Future Baseline, based on the 2009 SEIS that identified a significant cumulative traffic impact resulting from the proposed conversion. As a result, the recommended mitigation, as described in the 2009 SEIS, was to maintain two-way operation on Piikoi and Pensacola.

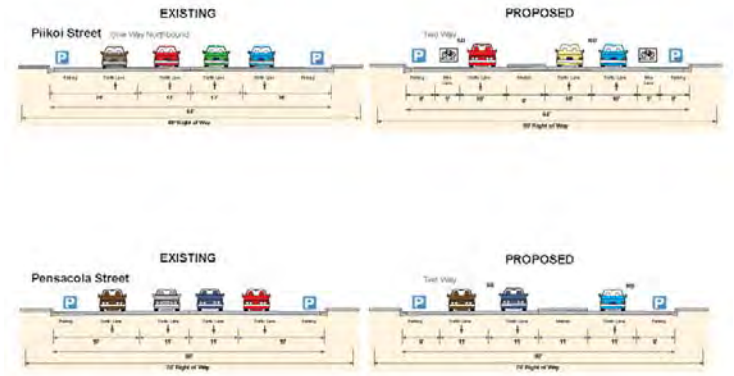
- As shown on Figures 25 to 27: no other changes to key roadways are anticipated under the Future Baseline Condition.

Figure 22 Planned / Proposed Roadway Network Changes (Future Baseline Condition)



Note: The Queen Street connection was constructed since the adoption of the Kaka`ako Muaka Area Plan Supplemental EIS Transportation Analysis.

Source: Kaka`ako Muaka Area Plan Supplemental EIS Transportation Analysis, April 14, 2009.



The proposed Piikoi/Pensacola two-way conversion is not included in the Future Baseline Condition analysis, based on the mitigations described in the 2009 Kaka`ako Muaka Plan SEIS.

Figure 23 Planned Roadway Network Changes (Future Baseline Condition)

Source: Kaka`ako Mauka Area Plan SEIS Transportation Analysis, April 14, 2009

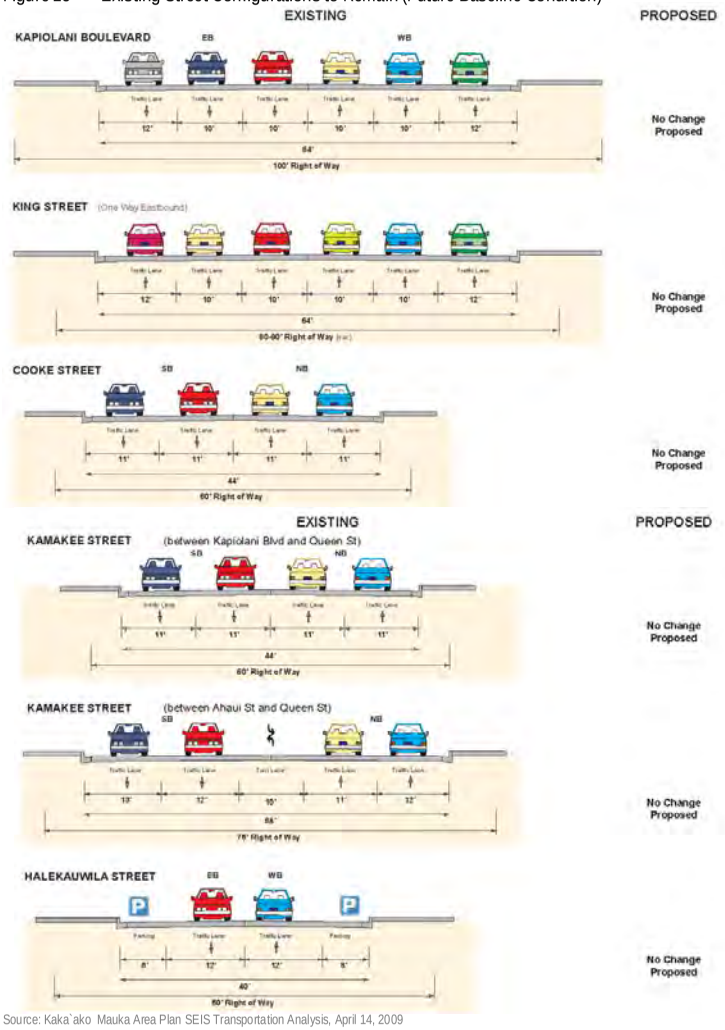


Figure 24 Existing Street Configuration to Remain – Pokoi / Pensacola (Future Baseline Condition)

Source: Kaka`ako Mauka Area Plan SEIS Transportation Analysis, April 14, 2009

Note: although the 2009 Plan recommended conversion of the existing one-way segments of Piikoi and Pensacola (north of Kapiolani Street) to two-way (as shown above on Figure 24), the 2009 SEIS Transportation Assessment included a mitigation removing the proposed 2-way conversion of Piikoi and Pensacola Streets from the 2009 Plan. Based on that mitigation, this assessment assumes the 1-way segments will remain under the Future Baseline Condition.

Figure 25 Existing Street Configurations to Remain (Future Baseline Condition)

3.3 TRAFFIC OPERATIONS – YEAR 2035 FUTURE BASELINE CONDITION

Traffic Volumes – Year 2035 Baseline (Future Baseline Condition)

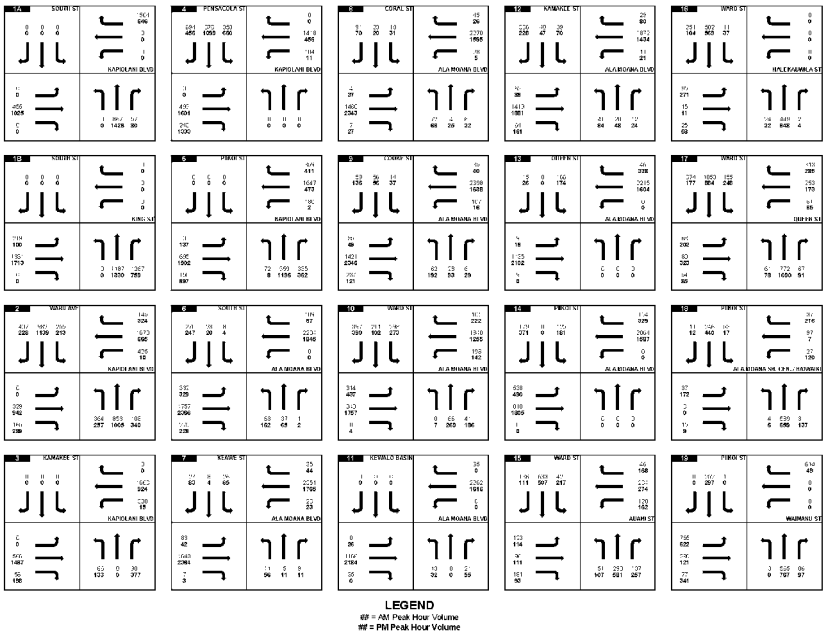
Year 2035 Baseline traffic volumes at each study intersection were estimated based on the anticipated net change in traffic volumes as determined by the OMPO model outputs. Forecast daily traffic volumes are summarized on Figure 28, and forecast AM and PM Peak Hour volumes are shown on Figures 29 to 31.

A comparison of Existing PM peak hour traffic volumes and the forecast Future Baseline Condition PM peak hour traffic volumes yields the following findings:

- Traffic volumes at study intersections in the PM peak hour would be an average of 12 percent higher in the Future Baseline Condition alternative than under Existing Conditions.
- The largest increases in PM Peak Hour intersection volumes under the Future Baseline Condition would occur at the following five intersections, where the total 4-way approach volume is forecasted to increase by over 1,000 vehicles (representing an increase of over 30 percent at these locations):
  - Pensacola at Kapiolani
  - Ward at Kapiolani
  - Ward at Auhi
  - Ward at Queen
  - Cooke at Queen
- PM Peak Hour volumes at intersections on Ala Moana Boulevard are forecast to increase within a range varying from approximately 250 to 600 vehicles per intersection – representing an increase in volume at each intersection varying between approximately 7 to and approximately 14 percent as compared to Existing volumes.

Figure 28 Daily Traffic Volumes, Year 2035 Baseline (Future Baseline Condition)

Figure 29 Peak Hour Intersection Traffic Volumes, Year 2035 Baseline (Future Baseline Condition)



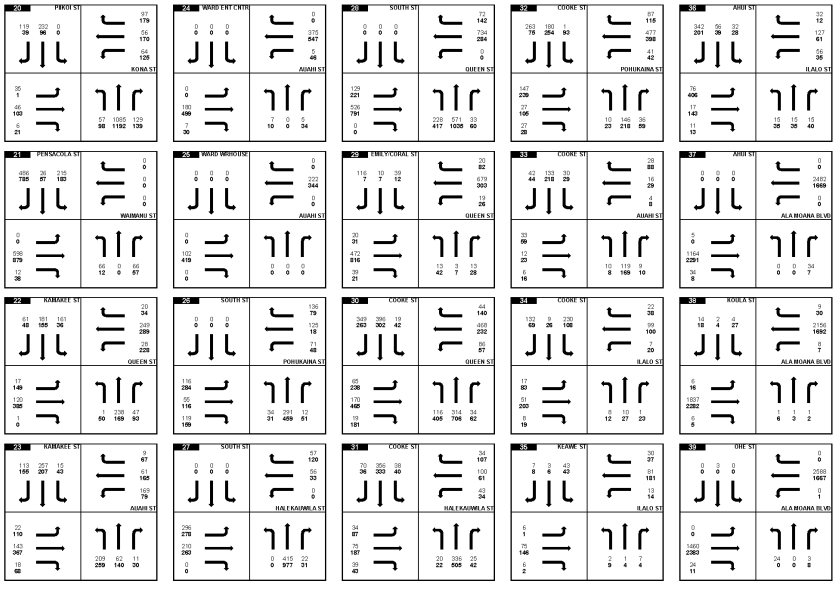


Figure 30 Peak Hour Intersection Traffic Volumes, Year 2035 Baseline (Future Baseline Condition)

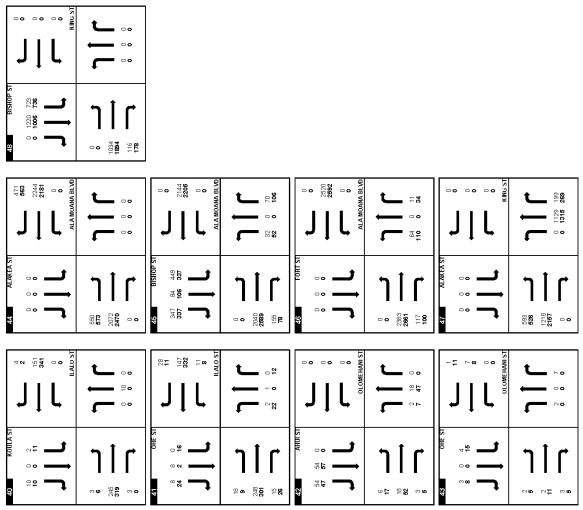

Figure 31 Peak Hour Intersection Traffic Volumes. Year 2035 Baseline (Future Baseline Condition)

Intersection Level of Service (Future Baseline)

Based on the forecast peak-hour traffic volume under Year 2035 Baseline conditions, the anticipated LOS was determined for each study intersection. Table 13 provides a comparison of Existing and Year 2035 Baseline (Future Baseline Condition) LOS at each study intersection during the AM and PM Peak Hours.

Table 13 Peak Hour Intersection Level of Service, Year 2035 Baseline (Future Baseline Condition)

3.4 PUBLIC TRANSIT – YEAR 2035 FUTURE BASELINE CONDITION

Planned Transit

Honolulu Authority for Rapid Transit (HART) is building an elevated rapid transit line that will serve the City and County of Honolulu. The system will begin in East Kapolei and connect with the Honolulu International Airport and downtown Honolulu, ending at Ala Moana Center. Ridership is estimated at 116,300 weekday passenger trips by the year 2030, with trains arriving every three minutes during peak travel times, every six minutes during the day, and every ten minutes in the evenings.

The light rail system is scheduled to be in full operation by 2019 and is therefore included in the transit analysis because it will provide significant new transit capacity to the study area. The initial section of the rail transit system, from Kapolei to Aloha Stadium, is slated to open in 2017; the entire system, from Kapolei to Ala Moana Center, is scheduled to open in 2019.

The introduction of rapid transit to the KCDD will significantly change the dynamic for access to the district and mobility between the district and adjacent areas on the line. Much of the Mauka neighborhood is within 5 to 10 minute walking distance(approximately .25 to .5 miles) of the three planned HART rapid transit stations in the District, (see TOD Overlay Plan Figure 5-12). These stations will provide a previously unattainable level of connectivity and convenience in travel for those moving between KCDD and many other parts of the Honolulu metro area. The stations will be:

- **Civic Center Station:** Located on Halekauwila Street between South and Keawe Streets, this station site is adjacent to land that is part of Kamehameha School's Kalaulu O Kaka`ako Master Plan area.
- **Kaka`ako Station:** This station is planned by the City to be located on property that is part of the Ward Neighborhood Master Plan. The station site is positioned on the corner of Ward Avenue and Queen Street and will operate as the closest stop to Kewalo Basin boat harbor, the Ewa side of Ala Moana Beach Park, the Diamond Head side of Kaka`ako Waterfront Park and the Blaisdell Arena, Exhibition and Concert Halls.
- **Downtown Station (at the Aloha Tower Special District):** Located adjacent to the Aloha Tower Special District. The City intends this station to serve Honolulu's Central Business District.

Additionally, the KCDD has significant access to TheBus transit service, with major service corridors provided on King, Kapolani, and Ala Moana. Stops on Punchbowl, King, and Ala Moana are among the busiest transit boarding locations in Honolulu.

The expected transit network after implementation of the fixed guideway system is illustrated in Figure 32.

Figure 32 Planned Transit Network (Year 2035 Future Baseline)

Kakaako Community Development District TOD Overlay Plan | FEIS Transportation Analysis
Hawaii Community Development Authority

Transit Ridership & Capacity, Year 2035 Future Baseline Condition

HART is expected to substantially increase capacity in the west and east screenlines. HART is also expected to draw new riders to transit because planned improvements in speed, reliability, and frequency, thus causing an increase in ridership across the west screenline.

As shown on Table 14, under the Future Baseline Condition, capacity utilization in the AM and PM peak periods is still well below the 80 to 90 percent threshold of significance for this analysis (this is the same threshold that was identified in the 2009 EIS) . Figures 33 and 34 summarize screenline capacity utilization for AM and PM peak hour transit capacity.

Table 14 Future Baseline Condition Transit Capacity Utilization

	Existing Conditions			Future Baseline Condition		
Screenline	Ridership	Capacity	Capacity Utilization	Ridership	Capacity	Capacity Utilization
AM Beak Hour - Inbound						
East	2,943	6,720	44%	5,713	13,850	41%
West	4,635	10,500	44%	9,677	15,680	62%
North	351	480	73%	1,195	2,280	52%
Total	7,929	17,700	45%	16,585	31,810	55%
PM Peak Hour – Outbound						
East	2,915	6,300	46%	6,108	15,440	40%
West	4,645	10,590	44%	9,873	16,490	60%
North	440	660	67%	1,338	2,220	60%

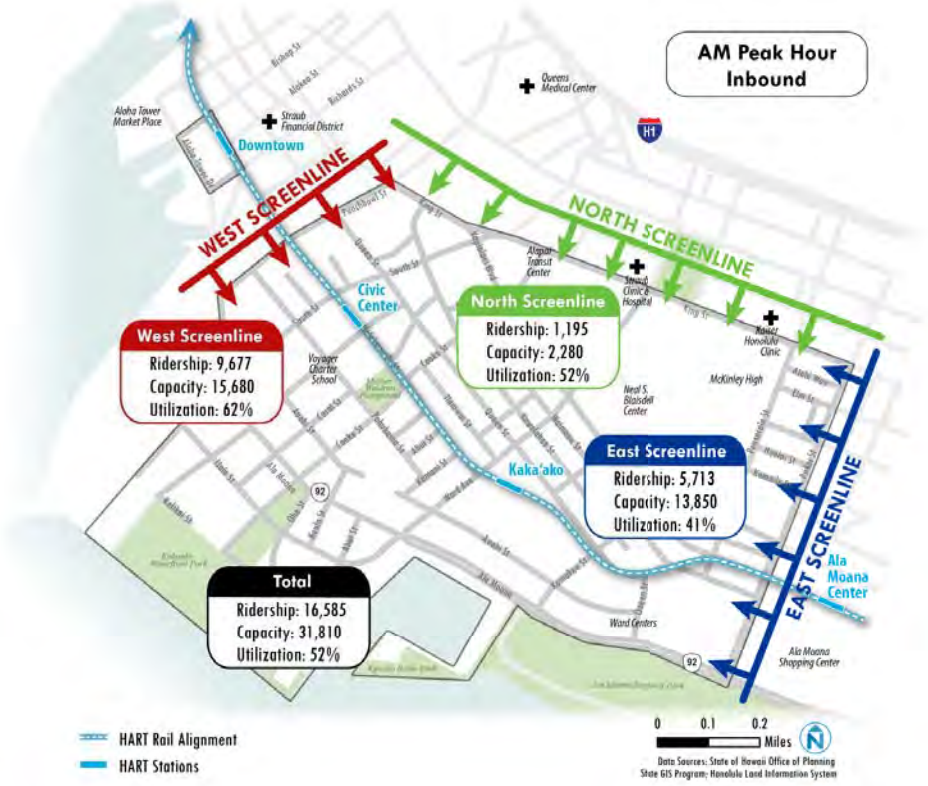
Figure 33 Future Baseline Condition Transit Capacity Utilization AM Peak Hour



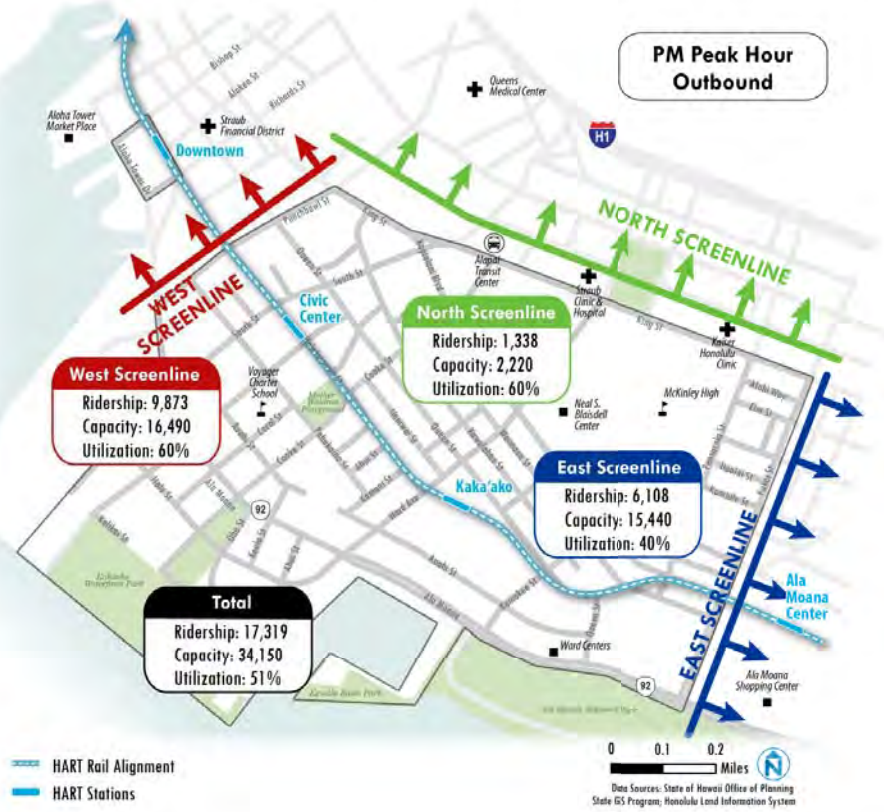


Figure 34 Future Baseline Condition Transit Capacity Utilization PM Peak Hour

3.5 BICYCLE CIRCULATION – YEAR 2035 FUTURE BASELINE CONDITION

Planned Bikeway Improvements (Future Baseline Condition)

The Future Baseline Condition alternative applies the proposed street network improvements from the existing Mauka and Makai Area Plans. As shown on Figures 23 to 27:

- No bicycle lanes are included in the Future Baseline Condition, based on the proposed street changes identified in the 2009 SEIS.

Based on the Mauka Area Plan EIS process in 2009, the following bikeway improvements were proposed for the project area:

- Suggested future restriping of existing four-lane roadways to accommodate bicycle lanes (but specific corridors were not identified at that time)
- Recommended change Cooke Street, Pohukaina Street, and Kamakee Street into bicycle-friendly streets that allow for safe bicycle connections to existing open space in the area (but no project extent, bikeway type, or facility recommendation was identified).

Forecasted Volume of Bicycle Trips (Future Baseline Condition)

Compared to the Existing condition, the Future Baseline Condition is expected to generate an additional 1,030 bicycle trips in the AM peak period and an additional 1,387 bicycle trips in the PM peak period. However, the projected increase in bicyclists is not yet supported by targeted safety or connectivity improvements under the Future Baseline Condition.

3.6 PEDESTRIAN CIRCULATION – YEAR 2035 FUTURE BASELINE CONDITION

Planned Pedestrian Improvements (Future Baseline Condition)

The Future Baseline Condition (existing Mauka and Makai Area Plans) proposes crosswalks at all intersections and sidewalks along all or most streets. These improvements are intended to better orient Kaka`ako's streets and buildings to pedestrians, an improve pedestrian safety, particularly in Central Kaka`ako where many streets lack curbs and sidewalks.

In general, the Future Baseline Condition calls for a well-developed network of pedestrian-friendly streets with wide, landscaped sidewalks and active building frontage that invites pedestrian traffic. Cooke Street, Pohukaina Street, and Kamakee Street are designated as "green" streets and connect pedestrians and bicyclists with park and open space facilities.

Several streets like Auahi Street, Pohukaina Street, Ala Moana Boulevard, Punchbowl Street, Cooke Street, and Kamakee Street are planned to undergo "Promenade" treatments with 15-foot sidewalks. This would be accomplished by a combination of either curb-to-curb width reduction and/or requiring redevelopment setbacks.

The Future Baseline Condition also proposes intersection improvements at:

- Cooke Street / Ala Moana Boulevard;
- Ward Avenue / Queen Street;

- Ward Avenue / Pohukaina Street;
- Ward Avenue / Ala Moana Boulevard;
- Kamakee Street / Ala Moana Boulevard; and,
- Piikoi Street / Ala Moana Boulevard.

These six intersections would be reconstructed with high visibility crosswalk design—such as ladder striping, flashing beacons, and improved signage—in order to encourage mauka-makai connectivity and improve crossing safety across major thoroughfares. The Future Baseline Condition also proposed planters, street furniture such as benches, and on-street parking to help create a buffer zone between pedestrians and street traffic.

The planned widening of Ala Moana Boulevard from 72 to 84 feet (identified as a mitigation in the 2009 SEIS) would increase pedestrian crossing distances under Year 2035 conditions.

Forecasted Volume of Pedestrian Trips (Future Baseline Condition)

Compared to the Existing condition, the Future Baseline Condition is expected to generate an additional 4,637 pedestrian crossings in the AM peak period and an additional 6,239 pedestrian crossings in the PM peak period. Given the projected increase in pedestrian crossings spread across the project area's pedestrian network, the lack of sidewalks along various industrial streets and pedestrian delay at some arterial signalized intersections could limit pedestrian circulation at some locations under the Future Baseline Condition.

FUTURE CONDITIONS WITH TOD ALTERNATIVE A

This section provides a comparison of travel conditions in Year 2035 under the TOD Alternative A (Draft TOD Overlay Plan). The travel demand forecast under Year 2035 conditions was derived from the Regional Model, based on the projected level of development under the TOD Alternative A.

4.1 TRIP GENERATION & TRAVEL MODES

Travel Demand Forecast – TOD Alternative A

The OMPO model was utilized to provide a forecast of trip generation based on Future Baseline Condition and TOD Alternative A (Year 2035 TOD Plan) land uses. The net change to trip generation was derived based on existing land uses under the OMPO Model Year 2015 Baseline scenario. Table 15 provides a summary of the travel demand forecast.

Table 15 Travel Demand Comparison

	Existing Condition (2015 Model Base Year)	Future Baseline Condition (2035 Model Baseline)	Future Baseline + TOD Alternative A (2035 TOD Overlay)
Households	11,867	38,221	51,393
Net Change from Existing		26,354	39,526
Percent Increase over Existing		222%	333%
Retail Employment	7,916	16,840	15,706
Non-Retail Employment	28,303	44,739	39,923
Total Daily Person Trips	286,878	569,295	679,059
Net Change from Existing		282,417	392,181
Percent Increase over Existing		98%	136%
Internal Capture	36.7%	51.3%	53.2%
External Person Trips (daily)	181,594	277,247	317,800
Net Change from Existing		95,653	136,206
Percent Increase over Existing		53%	75%

Based on the travel demand model forecast:

- **Total volume of travel:** Total daily person trips by all modes traveling to, from, or within the study area, would essentially double under the Future Baseline Condition, with a 98 percent increase over the Existing Condition. Under the TOD Alternative A, total daily person trips by all modes would increase by 136 percent over the Existing Condition.

- **Trips internal to the study area:** The portion of trips internal to the study area would increase from 36 percent under Existing Conditions to 51 percent under the Future Baseline Condition, with a further increase to 53 percent under the TOD Alternative A.

Travel Mode Comparison – TOD Alternative A

Table 16 provides a comparison of travel mode choice predicted by the OMPO model forecast, which indicates that:

- Walk and bike trips would increase from 15.5 percent of total daily trips under Existing Conditions to:
  - 20.1 percent under the Future Baseline Condition
  - 21.7 percent of daily trips under the TOD Alternative A
- Motor vehicle trips would decrease from 77.3 percent of total daily trips under Existing Conditions to:
  - 71.3 percent of under the Future Baseline Condition
  - 69.6 percent under the TOD Alternative A
- Transit trips would increase from 7.2 percent of total daily trips under Existing Conditions to 8.7 percent under both the No Action and TOD Alternative A.

Table 16 Travel Mode Comparison – TOD Alternative A

	Existing Conditions (2015 Model Base Year)	Future Baseline Condition (2035 Model Baseline)	Future Baseline + TOD Alternative A (2035 TOD Overlay)
Public Transit	7.2%	8.7%	8.7%
Walk + Bike	15.5%	20.1%	21.7%
Motor Vehicles	77.3%	71.3%	69.6%

Source: OMPO model with Changes to Land Uses within KCDD

Trip Generation Forecast – TOD Alternative A

The OMPO model forecast of daily motor vehicle, transit and bike/walk trips under Existing and Year 2035 conditions, under both the Future Baseline Condition and TOD Alternative A, is shown on Table 17.

Based on this forecast, the TOD Alternative A will generate the following net increases in trips in comparison to the Future Baseline Condition:

- Walk/bike trips: 29 percent increase over the Future Baseline Condition
- Transit trips: 19 percent increase over the Future Baseline Condition
- Motor vehicle trips: 16 percent increase over the Future Baseline Condition based on daily trips, while the increase in peak-hour motor vehicle trips would be smaller:
  - 7 percent increase over the Future Baseline Condition during the AM Peak Hour
  - 9 percent increase over the Future Baseline Condition during the PM Peak Hour

Table 17 Trip Generation Forecast – TOD Alternative A

	Motor Vehicle Trips			Transit Trips	Walk/ Bike Trips
	AM Peak Hour	PM Peak Hour	Daily	Daily	Daily
Total Trip Generation					
Existing Land Uses	13,822	9,249	184,797	20,655	44,466
Future Baseline Condition	25,380	28,313	338,256	49,528	114,428
Future Baseline + TOD Alternative A	27,191	30,783	393,854	59,078	147,356
Pct Increase over Existing	*97%*	*233%*	*113%*	*186%*	*231%*
Pct Change over Future Baseline Condition	*7%*	*9%*	*16%*	*19%*	*29%*
Net Trip Generation Comparison					
Future Baseline Condition	11,558	19,064	153,459	28,873	69,962
Future Baseline + TOD Alternative A	13,369	21,534	209,057	38,423	102,890
TOD Alternative A : Net Change over Future Baseline	*1,811*	*2,470*	*55,598*	*9,550*	*32,928*

4.2 ROADWAY NETWORK CHANGES – TOD ALTERNATIVE A

Potential changes to the roadway network under the TOD Alternative A are described in the Draft TOD Overlay Plan include:

- Proposed roadway network connections to facilitate internal circulation within the KCDD as shown on Figure 35.
  - Analysis of the proposed restoration of two-way operation on Piikoi and Pensacola Street was excluded from the analysis because the regional-serving character of the roadways, with their direct connections to the H-1 freeway, is beyond the scope of the present analysis.
- Designation of priority streets for Motor Vehicles, Bicycles, and Pedestrians as shown on Figures 36 to 38.

Figure 35 Action Alternative – Proposed Street Connections

Figure 36 Action Alternative – Proposed Motor Vehicle Priority Streets

Figure 37 Action Alternative – Proposed Bicycle Priority Streets

Figure 38 Action Alternative – Proposed Pedestrian Priority Streets

4.3 TRAFFIC IMPACTS

Traffic Volumes

Based on the anticipated change in traffic volumes comparing the TOD Alternative A model results to the Future Baseline Condition, the anticipated distribution of daily traffic volumes are shown on Figure 39. Detailed intersection volumes for each of the key study area intersections are shown on Figures 40 through 42.

Figure 39 Year 2035 Traffic Volumes on Key Corridors (TOD Alternative A)

Intersections shown in bold operate at LOS F under the Future Baseline Condition and TOD Alternative A.

*LOS as shown reflects downstream delay.
**Intersection LOS based on planned signalization described as mitigation in 2009 EIS.

Kakaako Community Development District TOD Overlay Plan | FEIS Transportation Analysis
Hawaii Community Development Authority

Traffic Impact Findings

Traffic impacts are considered significant if:

- The TOD Alternative A causes the level of service to deteriorate from LOS E or better under the Future Baseline Condition to LOS F under the TOD Alternative A.

There are no intersections in the study area which would deteriorate from LOS E or better under the Future Baseline Condition to LOS F under the TOD Alternative A.

- Traffic impacts are also considered significant if the operational impacts on signalized intersections operating at LOS F under both the Future Baseline Condition and TOD Alternative A are considered significant if the volume to-capacity (v/c) ratio under the TOD Alternative A exceeds that of the Future Baseline Condition.

The following study intersections would operate at LOS F under both the Future Baseline Condition and TOD Alternative A:

- Ala Moana & South (study intersection #6)
- Ala Moana & Cooke (study intersection #9)
- Ala Moana & Ward (study intersection #10)
- Queen & Ward (study intersection #17)
- Kapiolani & Ward (study intersection #2)

Additional study intersections would operate acceptably based strictly on volume/capacity ratios at each intersection, but could be impacted by downstream delay at adjacent intersections on Ala Moana Boulevard west of Ward Street:

- Ala Maona & Keawe (study intersection #7)
- Ala Moana & Coral (study intersection #8)
- Ala Moana & Koula (study intersection #38)

The identified intersections were analyzed as described in the next section to determine whether significant traffic impacts may exist.

Findings of Significance at Impacted Intersections

Ala Moana & South

Intersection is forecast to operate at LOS F under peak-hour conditions based on the Year 2035 traffic forecast under both the Future Baseline Condition and TOD Alternative A. Since the volume to-capacity (v/c) ratio under the TOD Alternative A exceeds that of the Future Baseline Condition, this impact is significant.

Finding: potentially significant.

Ala Moana & Keawe

The volume to-capacity (v/c) ratio at this intersection would be acceptable under both the TOD Alternative A and Future Baseline Condition. However, downstream delay results in delay that could affect the operation of this intersection.

Finding: less than significant.

Ala Moana & Coral

The volume to-capacity (v/c) ratio at this intersection would be acceptable under both the TOD Alternative A and Future Baseline Condition. However, downstream delay results in delay that could affect the operation of this intersection.

Finding: less than significant.

Ala Moana & Cooke

Intersection is forecast to operate at LOS F under peak-hour conditions based on the Year 2035 traffic forecast under both the Future Baseline Condition and TOD Alternative A. Since the volume to-capacity (v/c) ratio under the TOD Alternative A exceeds that of the Future Baseline Condition, this impact is significant.

Finding: potentially significant.

Ala Moana & Koula

The volume to-capacity (v/c) ratio at this intersection would be acceptable in both the TOD Alternative A and Future Baseline Condition. However, downstream delay results in delay that could affect the operation of this intersection.

Finding: less than significant.

Ala Moana & Ward

Intersection is forecast to operate at LOS F under peak-hour conditions based on the Year 2035 traffic forecast in both the Future Baseline Condition and TOD Alternative A. Since the volume to-capacity (v/c) ratio in the TOD Alternative A exceeds that of the Future Baseline Condition, this impact is significant.

Finding: potentially significant.

Queen & Ward

Intersection is forecasted to operate at LOS F under peak-hour conditions based on the Year 2035 traffic forecast in both the Future Baseline Condition and TOD Alternative A. Since the volume to-capacity (v/c) ratio under the TOD Alternative A exceeds that of the Future Baseline Condition, this impact is significant.

Finding: significant and unavoidable impact (SU). No feasible mitigations as described in the 2009 EIS.

Kapiolani & Ward

Intersection is forecast to operate at LOS F under peak-hour conditions based on the Year 2035 traffic forecast in both the Future Baseline Condition and TOD Alternative A. Since the volume to-capacity (v/c) ratio under the TOD Alternative A exceeds that of the Future Baseline Condition, this impact is significant. The 2009 EIS included the finding that no mitigation would be feasible at this intersection; therefore this impact was identified as significant and unavoidable.

Finding: potentially significant.

4.4 TRANSIT IMPACTS

The fixed guideway transit system – HART - is currently in the planning stages for the congested east-west corridor between Kapolei and UH Manoa. HART will provide faster, more reliable transit along the corridor where many transit vehicles must operate in mixed-flow traffic, and serve as an attractive alternative to the private automobile. The project would strengthen the connection between Kapolei, Downtown Honolulu and Kakaako, UH Manoa, and Waikiki.

A major goal of the TOD Alternative A is to encourage transit oriented development, designed to facilitate and encourage transit use by placing relatively high-density development adjacent to or within easy walking access of major transit facilities such as stations on the fixed guideway system or transfer points between bus lines. TOD projects also typically encourage the use of non-motorized modes of travel, including pedestrian and bicycle travel, and discourage the use of private automobiles.

Figure 43 provides an overview of the Year 2035 transit network under both the Future Baseline Condition and TOD Alternative A scenario.

Transit Ridership & Capacity – Year 2035 (TOD Alternative A)

Because the fixed guideway system will operate along an east-west alignment through the Mauka Area, it was assigned to both the east and west screenlines for the TOD Alternative A transit analysis. TOD Alternative A capacity was taken from the 2009 EIS. TOD Alternative A ridership was estimated using the following assumptions:

- Based on a comparison of the Future Baseline Condition (2035 Baseline) and TOD Alternative A (2035 TOD Plan) outputs from the OMPO model, the TOD Alternative A will generate approximately 10,000 additional transit riders per day (net change compared to the Action).
- The assumption was made that 10 percent of daily transit trips will occur during the peak-hour. Therefore, 10,000 daily riders would correlate to 1,000 peak-hour riders in the AM peak and 1,000 peak-hour riders in the PM.
- Using the model, the 1,000 additional trips were assigned to the east, west, and north screenlines proportionally.

The resulting capacity and utilization for the TOD Alternative A transit analysis is presented in Table 19 on page 86.

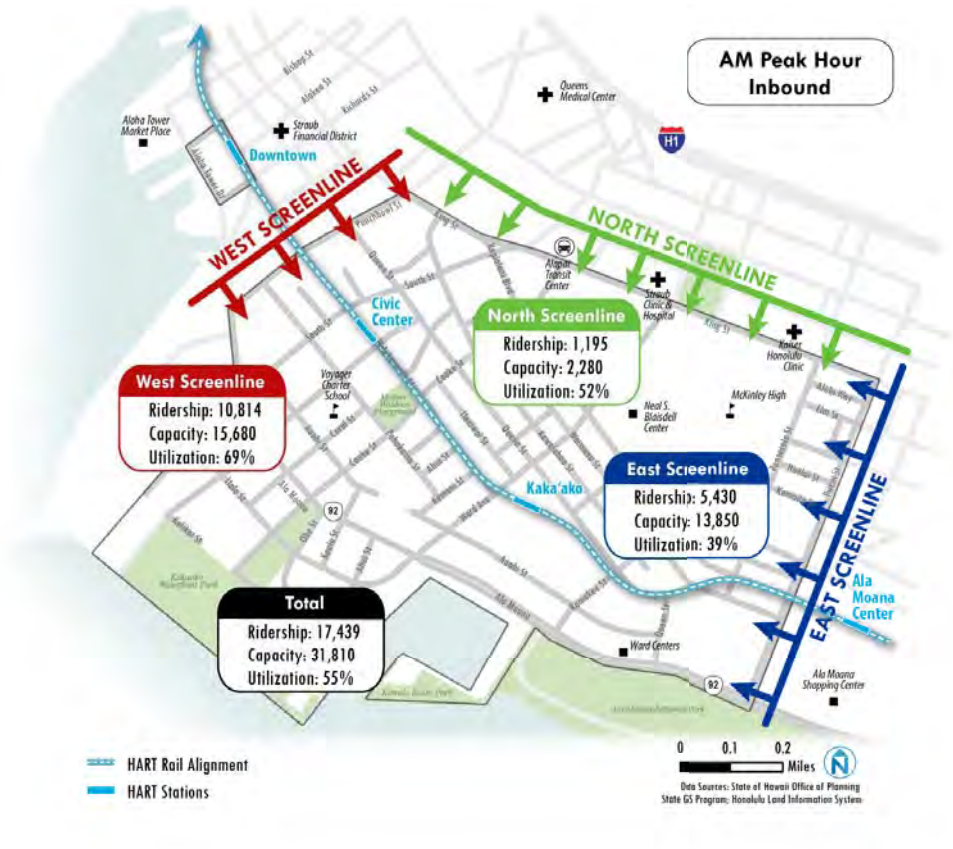
Total	7,929	17,700	45%	16,701	31,810	53%	17,439	31,810	55%
PM Peak Hour – Outbound									
East	2,915	6,300	46%	6,194	15,440	40%	5,825	15,440	38%
West	4,645	10,590	44%	9,954	16,490	60%	11,010	16,490	67%
North	440	660	67%	1,341	2,220	60%	1,341	2,220	60%
Total	8,000	17,550	46%	17,489	34,150	51%	18,173	34,150	53%

Source: Existing and Future Baseline Condition (2009 EIS); TOD Alternative A (Ridership from the OMPO model; Capacity from the 2009 EIS)

As shown in Error! Reference source not found., the fixed guideway system is expected to substantially increase capacity in the west and east screenlines. The guideway system is also expected to draw new riders to transit because of its improvement over existing bus services in terms of speed, reliability, and frequency, thus causing an increase in ridership across the west screenline. Given the increased capacity from the fixed guideway system, however, utilization will still be below the 80 to 90 percent threshold typically considered acceptable for urban areas. Peak hour screenline results are summarized on Figures 44 and 45.

Figure 44 Transit Capacity Utilization – AM Peak Hour (TOD Alternative A)



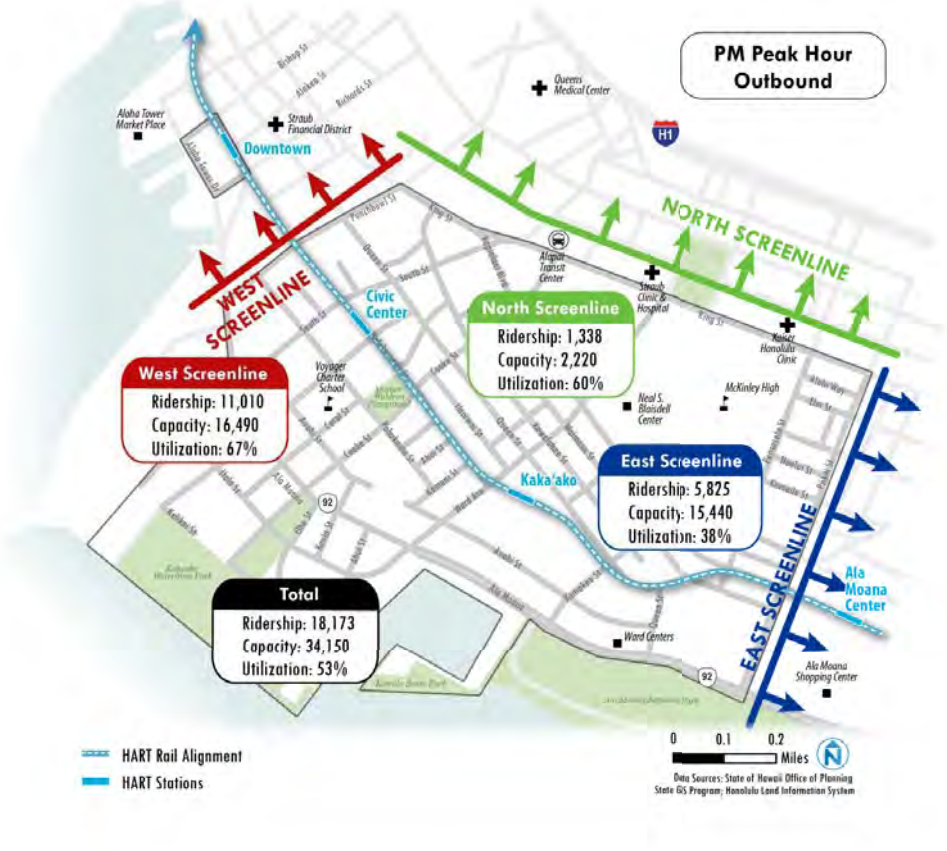


Figure 45 Transit Capacity Utilization – PM Peak Hour (TOD Alternative A)

Kakaako Community Development District TOD Overlay Plan | FEIS Transportation Analysis
Hawaii Community Development Authority

Transit Impact Findings

Based on the transit impact criteria described in the 2009 EIS, transit impacts are considered significant if:

- The plan causes a substantial increase in transit demand that could not easily be accommodated by available transit capacity, resulting in unacceptable levels of transit crowding. Capacity utilization above 80 to 90 percent is generally considered unacceptable for urban transit services.
- The plan causes a substantial increase in operational delay or costs that could result in adverse impacts to transit service.

The fixed guideway system is expected to substantially increase capacity on the west and east screenlines. The capacity utilization on all screenlines (north, east, and west) in the AM and the PM peak is not expected to exceed 69%. Therefore, there is no significant transit impact resulting from the TOD Alternative A and no additional mitigations are required.

Regarding operational delay, traffic delay under the TOD Alternative A is not anticipated to result in a level of delay to buses that would require additional buses or operating costs compared to the Future Baseline condition. Therefore, there is no significant transit operations impact resulting from the TOD Alternative A and no additional mitigations are required

4.5 BICYCLE IMPACTS

Recommended Bicycle Network Changes (Draft TOD Overlay Plan)

The TOD Alternative A elevates several bikeway types as compared to the Future Baseline Condition to ensure greater separation from motor vehicle traffic, and proposes additional bikeways to facilitate east-west and north-south bicycle connectivity and safe bicycle operation. The Draft TOD Overlay Plan recommends the following revisions to the Future Baseline Condition bicycle network:

- Bike lanes on King Street from Piikoi Street to Punchbowl Street
- Cycle track (path)[1] or bike lanes on Ala Moana Boulevard from Piikoi Street to the ewa edge of the Aloha Tower Special District
- Cycle track (path) or bike lane couplet on Punchbowl Street and South Street between King Street and Ala Moana Boulevard
- Signed and marked bike route on Queen Street from Kamakee Street to Punchbowl Street
- Cycle track (path) or bike lanes on Halekauwila Street from Ward Avenue to the Diamond Head edge of the Aloha Tower Special District
- Signed and marked bike route on Auahi Street from Ala Moana Boulevard to Ward Avenue
- Signed and marked bike route on Ilalo Street from Ahui Street and Keawe Street
- Bike lanes on Cummins Street (developed with proposed street extension)
- Bike lanes on Ward Avenue from King Street and Ala Moana Boulevard
- Bike lanes on Kamakee Street between Kapiolani Boulevard and Ala Moana Boulevard
- Cycle track (path) or bike lane couplet on Pensacola Street from King Street to Punchbowl Street and Piikoi Street from King Street to Ala Moana Boulevard
- Signed and marked bike routes on Pohukaina Street from Ward Avenue to Punchbowl Street
- Bike path connecting the Ala Moana Regional Park multi-use path to the Kaka`ako Waterfront Park multi-use path(via Ahui Street)
- Bike path between the Neil S. Blaisdell Center and McKinley High School connecting the Kamakee Street end with King Street

The recommended improvements listed above and displayed in Figure 46 only cover bikeway project extents within the project area. These recommended improvements are not stipulated as part of the TOD Alternative A because HCDA does not have jurisdiction over streets in Kaka`ako. Thus, the recommendations in the Draft TOD Overlay Plan are only strategies and are not required improvements. The following sections summarize the impacts created as part of the TOD Alternative A and provide more targeted mitigation measures tied to the stated impacts.

[1] A cycle track is a dedicated bicycle facility type that is physically separated from adjacent travel lanes by bollards, planters, on-street parking, curbs, or any other raised material. Cycle tracks can be situated at street level, between sidewalk and street level, or at sidewalk level.

Kakaako Community Development District TOD Overlay Plan | FEIS Transportation Analysis
Hawaii Community Development Authority

Figure 46 Recommended Bicycle Priority Streets from the Draft TOD Overlay Plan

Note: Because HCDA does not have jurisdiction over streets in Kaka`ako, recommendations in the Draft TOD Overlay Plan are only strategies and not required improvements.

Summary Findings of Significance

The following list encapsulates the potential impacts that could be observed along key bicycle corridors throughout the project area, as many corridors exhibit a variety of impacts. These impact types are based on the significance criteria listed in Section 1.3, the change in bicycling movements between the Future Baseline Condition and TOD Alternative A, and the ability of the Future Baseline Condition to connect the forecast increase in bicyclists with existing and new destinations based on the Year 2035 Land Use Comparison.

- Threefold increase in daily bicycle volumes with no commensurate or appropriate increase in bicycle capacity.
- Lack of east-west connectivity to support the substantial increase in bicycle volumes (definition of substantial increase depends on the corridor).
- Lack of north-south connectivity to support the substantial increase in bicycle volumes (definition of substantial increase depends on the corridor).
- Lack of bicycle facilities to facilitate access to all three rail stations.
- Substantial increase in turn volumes at a number of intersections along key bicycle corridors increases exposure to collision.

Compared to the Future Baseline Condition, the TOD Alternative A is expected to generate an additional 485 bicycle trips in the AM peak period and an additional 652 bicycle trips in the PM peak period. The increase in AM and PM peak period bicycle movements is summarized in Table 20.

Table 20 Bicycle Volumes – TOD Alternative A

	Existing Condition (2015 Model Baseline)	Future Baseline Condition (2035 Model Baseline)	Future Baseline + TOD Alternative A (2035 TOD Overlay)	Future Baseline + TOD Alternative A (Percent Change over Existing)	TOD Alternative A (Percent Change over Future Baseline)
Daily	8,084	20,805	26,792	231%	29%
AM Peak Hour	654	1,685	2,170	231%	29%
PM Peak Hour	881	2,267	2,920	231%	29%

Bicycle Impact Findings

The following corridors would exhibit impacts in as a result of the TOD Alternative A based on one or more of the potential impacts listed in the section above. *In each impacted corridor, a 331% increase in peak period bicycle volumes (from existing bicycle volumes to TOD Alternative A conditions) and a 129% increase in peak period bicycle volumes (from Future Baseline Condition bicycle volumes to TOD Alternative A conditions) with no corresponding available bicycle capacity triggers a significant impact.* Although bike sharing is not included in the analysis, bike share implementation (projected to produce between 1.6 and 2.1 million trip per year) will make the lack of bicycle capacity an even more severe issue. In addition, because none of the corridors that offer direct travel are furnished with dedicated bicycle facilities, increased auto turn volumes are assumed to create a potentially significant impact.

Punchbowl Street

As part of the South-Punchbowl one-way couplet, Punchbowl Street is a critical southbound bicycle connection on the ewa boundary of the project area. The projected increase in bicycle volumes along Punchbowl Street is not supported by dedicated bicycle facilities. Punchbowl Street is also a key bicycle access route to future HART stations for bicyclists originating mauka of the H1 freeway. Each of these factors and the increase in bicycle volume between the Future Baseline Condition and TOD Alternative A contributes to a significant impact.

Finding: Potentially significant

South Street

As part of the South-Punchbowl one-way couplet, South Street is a critical northbound bicycle connection on the ewa boundary of the project area. This corridor currently accommodates up to 440 daily bicycle movements.[2] The projected increase in bicycle volumes (AM, PM, and daily bicycle trips) along South Street is not supported by dedicated bicycle facilities. South Street is also a key bicycle access route from the future HART Civic Center Station for bicyclists destined for points mauka of the H1 freeway. Each of these factors and the increase in bicycle volumes between the Future Baseline Condition and TOD Alternative A contributes to a significant impact.

Finding: Potentially significant

Cooke Street

Cooke Street is a critical north-south bicycle connection that provides direct access to the future HART Civic Center Station. This corridor currently accommodates up to 512 daily bicycle movements. Cooke Street is anticipated to exhibit a 48% increase in motor vehicle turn volumes at Pohukaina Street, which will increase bicycle exposure to turn conflicts. Because this is a key transit access route, there is an effective increase in bicycle conflicts, and there is a substantial projected increase in bicycle volumes (both due to demand for transit access and intra-district travel), Cooke Street's lack of dedicated bicycle facilities with a corresponding increase in bicycle volume between the Future Baseline Condition and TOD Alternative A contributes to a significant impact.

Finding: Potentially significant

Ward Avenue

Bisecting the project area, Ward Avenue is a key north-south bicycle connection that provides direct access to the future HART Kaka`ako Station and facilitates bicycle movement between the project area and areas mauka of the H1 freeway. This corridor currently accommodates up to 880 daily bicycle movements. Because this is a key transit access route, and there is a substantial projected increase in bicycle volumes between the Future Baseline Condition and TOD Alternative A (both due to demand for transit access and intra-district travel), Ward Avenue's lack of dedicated bicycle facilities is considered a significant impact.

Finding: Potentially significant

[2] Daily bicycle movements were extrapolated from AM and PM peak period (2-hour) bicycle counts.

Halekauwila Street

Although Halekauwila Street currently only accommodates up to 288 daily bicycle movements, this corridor will serve as a critical east-west bicycle connection. Given its alignment under the HART rail alignment, Halekauwila Street provides direct access to the future HART Civic Center, Kaka`ako, and Downtown Stations. Because this is a key transit access route, and there is a substantial projected increase in bicycle volumes between the Future Baseline Condition and TOD Alternative A (both due to demand for transit access and intra-district travel), Halekauwila Street's lack of dedicated bicycle facilities with a corresponding increase in bicycle volume between the Future Baseline Condition and TOD Alternative A contributes to a significant impact.

Finding: Potentially significant

Pensacola Street

Pensacola Street is a critical southbound bicycle connection at the Diamond Head edge of the project area. This corridor currently accommodates up to 288 daily bicycle movements. The projected increase in bicycle volumes along Pensacola Street between the Future Baseline Condition and TOD Alternative A is not supported by dedicated bicycle facilities. Pensacola Street is also a key bicycle access route to two future HART stations (Kaka`ako Station and Ala Moana Station) and Ala Moana Center for bicyclists originating from the Makiki neighborhood. Because this is a key transit access route, and there is a substantial projected increase in bicycle volumes between the Future Baseline Condition and TOD Alternative A (both due to demand for transit access and intra-district travel), Pensacola Street's lack of dedicated bicycle facilities is considered a significant impact.

The City and County has expressed interest in potentially converting the Pensacola-Piikoi one-way couplet into two-way operation while providing high quality bicycle facilities. This should be studied in the future.

Finding: Potentially significant

Piikoi Street

Piikoi Street is a critical northbound bicycle connection at the Diamond Head edge of the project area. This corridor currently accommodates up to 380 daily bicycle movements. Piikoi Street is anticipated to exhibit a 30% increase in motor vehicle turn volumes at Ala Moana Boulevard, which will increase bicycle exposure to turn conflicts. The projected increase in bicycle volumes along Piikoi Street between the Future Baseline Condition and TOD Alternative A is not supported by dedicated bicycle facilities. Piikoi Street is also provides bicycle egress from two future HART stations (Kaka`ako Station and Ala Moana Station) and Ala Moana Center, particularly for bicyclists destined for the Makiki neighborhood. Piikoi Street is anticipated to exhibit a 30% increase in motor vehicle turn volumes at Ala Moana Boulevard, which will increase bicycle exposure to turn conflicts. Because this is a key transit egress route, and there is a substantial projected increase in bicycle volumes between the Future Baseline Condition and TOD Alternative A (both due to demand for transit access and intra-district travel), Piikoi Street's lack of dedicated bicycle facilities is considered a significant impact.

The City and County has expressed interest in potentially converting the Pensacola-Piikoi one-way couplet into two-way operation while providing high quality bicycle facilities. This should be studied in the future.

Finding: Potentially significant

Additional Recommended Improvement (non-mitigation)

A bicycle and pedestrian crossing improvement at the King Street/Cooke Street intersection. is recommended as a potential *future* improvement measure. This would help link cyclists between the project area/Civic Center HART station and the Alapai Transit Center/Young Street signed and marked bike route (an east-west connection). This improvement is not recommended as a mitigation measure in this DEIS due to the location of the improvement relative to the project area.

4.6 PEDESTRIAN IMPACTS

Recommended Pedestrian Network Changes (Draft TOD Overlay Plan)

The pedestrian recommendations in the Draft TOD Overlay Plan seek to develop a high-quality pedestrian environment in the project area in order to achieve the goals of a lively, active, and transit-oriented community. Figure 47 illustrates where pedestrian investment is recommended as the district develops and the TOD Alternative A is realized. These recommended improvements are not stipulated as part of the TOD Alternative A as described in the Project Description. Thus, the recommendations in the Draft TOD Overlay Plan are only strategies and are not required improvements. The following sections summarize the impacts created as part of the TOD Alternative A and provide more targeted mitigation measures tied to the stated impacts.

The pedestrian priority types recommended in the Draft TOD Overlay Plan include:

- **Primary pedestrian priority streets** are those that connect key destinations in or adjacent to the district, including HART rail stations, and that will ultimately support active street front uses such as retail stores, public plazas, and entertainment venues. These streets require spacious sidewalks and a high level of pedestrian amenity.
- **Secondary pedestrian priority streets** are those that do not provide direct connections to major destinations or have very high traffic volumes. While these streets may never be ideal for walking along for long distances, they must still be safe enough to accommodate walking, and they should be easy and safe enough to cross that they do not serve as a barrier to pedestrians.
- **Low speed streets** are generally service streets that may have narrow widths and where pedestrians and traffic may even be asked to mix in a shared right-of-way. Note that the term "low speed streets" should not be interpreted to suggest that high-speeds are promoted anywhere in the project area.
- **Greenway connections** are streets where there is opportunity to connect parks, greenspace, and public plazas with well-landscaped, shaded, and interesting walking routes.

The following criteria were employed to develop the pedestrian priority network:

- ***Existing and anticipated pedestrian demand as a result of future redevelopment;***
- ***Key HART access streets for people walking to rapid transit stations;***

- ***Retail access or retail streets should prioritize pedestrian movement and create a welcoming environment to people walking to and between commercial/retail locations;***
- ***Locations where walking might be uncomfortable or where existing pedestrian infrastructure supply is inadequate for current or future demand.***

Other pedestrian network changes recommended in the Draft TOD Overlay Plan relate to conflict reduction, sidewalk expansion, and crossing distance reduction. Any street with on-street parking is proposed to include curb extensions at intersections. Driveway consolidation is proposed throughout the project area to reduce conflicts between motor vehicles and pedestrians and improve pedestrian safety. Building access is concentrated at smaller parking access or service streets in order to reduce search-for-parking traffic and eliminate conflicts with pedestrians. In addition, 5 feet of additional setback is recommended to achieve minimum 15 feet sidewalk widths. This is particularly critical in HART station areas, which will see an injection of pedestrian activity for at least 18 hours of the day. Mid-block crossings are also proposed to reduce some of the larger block sizes (those over 600-700 feet) and facilitate access to rail stations.

Kakaako Community Development District TOD Overlay Plan | FEIS Transportation Analysis
Hawaii Community Development Authority

Figure 47 Recommended Pedestrian Network from the Draft TOD Overlay Plan

Note: Recommendations in the Draft TOD Overlay Plan are only strategies and not required improvements.

Summary Findings of Significance

The following list encapsulates the potential impacts that could be observed along pedestrian corridors throughout the project area. These impact types are based on the significance criteria listed in Section 1.3, the change in pedestrian crossings between the Future Baseline Condition and TOD Alternative A, and the ability of the Future Baseline Condition to connect an increase in pedestrians with existing and new destinations based on the Year 2035 Land Use Comparison. Potential impacts for each corridor include:

- Threefold increase in daily pedestrian crossings with no commensurate or appropriate increase in pedestrian capacity.
- Pedestrian delay with the increase in pedestrian volumes (over 80 seconds of delay is the threshold for pedestrians). Average delay for all travelers is increasing because as traffic disperses across the network away from overcapacity streets like Ala Moana Boulevard
- Prevalence of long crossing distances (depends on curb-to-curb width and underutilization of pavement space). Shorter crossing distances (achieved by limited intersection skew, corner radii, and/or availability of curb extensions) increase the effective pedestrian queuing capacity at intersection corners.
- Lack of pedestrian facilities to facilitate access to all three rail stations.
- Lack of adequate sidewalks to meet future pedestrian demand.

Compared to the Future Baseline Condition, the TOD Alternative A is expected to generate an additional 2,182 pedestrian crossings in the AM peak period and an additional 2,937 pedestrian crossings in the PM peak period. The increase in AM and PM peak period pedestrian crossings is summarized in Table 21.

Table 21 Pedestrian Volumes – TOD Alternative A

	Existing Condition (2015 Model Baseline)	Future Baseline Condition (2035 Model Baseline)	Future Baseline + TOD Alternative A (2035 TOD Overlay)	Future Baseline + TOD Alternative A (Percent Change over Existing)	TOD Alternative A (Percent Change over Future Baseline)
Daily	36,381	93,622	120,564	231%	29%
AM Peak Hour	2,946	7,583	9,765	231%	29%
PM Peak Hour	3,965	10,204	13,141	231%	29%

Pedestrian Impact Findings

The following corridors would exhibit impacts in both the TOD Alternative A and Future Baseline Condition based on one or more of the potential impacts listed in the section above. In each impacted corridor, a 331% increase in peak period pedestrian crossings (from existing pedestrian crossings to TOD Alternative A conditions) and a 129% increase in peak period pedestrian crossings (from Future Baseline Condition pedestrian crossings to TOD Alternative A conditions) with no corresponding increase in pedestrian capacity triggers a significant impact. Some impacts are demonstrated throughout the district or along multiple corridors. These types of impacts are aggregated into a general "All corridors" category.

All corridors (district-wide impacts)

A number of corridors throughout the project area exhibit a range of impacts stemming from the project area's increase in pedestrian activity between the Future Baseline Condition and TOD Alternative A. These include:

- A limited number of dedicated crosswalk facilities along each corridor funnels pedestrian volumes to a limited number of crossing locations (triggering a capacity impact) or encouraging crossing at unmarked intersections or at unmarked mid-block locations (triggering a safety impact due to reduced pedestrian visibility).
- Current crossing distances extend pedestrian's exposure time to motor vehicles (triggering a safety impact) and reduce the person throughput of cross walk facilities (i.e., short crossings exhibit greater pedestrian crossing capacity per pedestrian phase).
- The increase in pedestrian volumes between the Future Baseline Condition and TOD Alternative A will create some crowding issues on various commercial corridors with sidewalks widths less than 10 feet.

Finding: Each impact listed above is potentially significant

Central Kaka`ako industrial streets

Because of the industrial character of Central Kaka`ako, most streets in this neighborhood are not furnished with sidewalks or curbs. In addition, delivery trucks, cars, and mopeds are parked in different patterns and even double parked. The lack of adequate sidewalk facilities and haphazard parking arrangement creates conflicts with pedestrians and reduces the potential utility of several direct and relatively calm streets that could provide access to future HART stations. These conditions, coupled with an increase in pedestrian volumes, factors into triggering an impact on streets like:

- Waimanu Street
- Kawalahao Street
- Queen Street
- Hopaka Street
- Coral Street
- Kona Street
- Cummins Street
- Kamani Street
- Ilaniwai Street

HCDA has worked with the Central Kaka`ako community and determined that the industrial character of the area should remain. Curbless, shared street designs should be sought in order to reduce conflicts, create pockets of pedestrian space and ensure safe coexistence of street space between all users.

Finding: Potentially significant

Ala Moana Boulevard (signal timing improvements)

Intersections along Ala Moana experience substantial pedestrian delay for an urban district. For the purposes of this assessment, over 80 seconds of delay is considered the impact threshold for pedestrians. Using Ala Moana's intersection with Ward Avenue as an example, this intersection exhibits 140 second signal cycles—70 seconds to Ala Moana, 70 seconds to Ward. This cycle timing is inefficient and creates unacceptable delay. Pedestrians crossing Ala Moana are provided 35 seconds per pedestrian phase with 7 seconds of GREEN WALK time. With the projected increase in pedestrian volumes between the Future Baseline Condition and TOD Alternative A, unmitigated pedestrian delay can compound sidewalk and intersection queuing capacity issues. This constitutes an impact.

Finding: Potentially significant

Ala Moana Boulevard (pedestrian improvements)

Ala Moana is not a key HART station access route, but it serves as the most direct east-west pedestrian and bicycle connection between Kaka`ako and Waikiki. This corridor currently accommodates up to 215 and 269 pedestrian crossings in the AM and PM peaks, respectively.[3] This is anticipated to increase threefold between the Existing and TOD Alternative A timeframes. Crossings between the Future Baseline Condition and TOD Alternative A are projected to increase 29%.

The likelihood of sidewalk riding by bicyclists due to the current traffic conditions can increase pedestrians' exposure to collisions with bicycles. With the simultaneous increase in pedestrians and bicyclists using sidewalks (because of the lack of bicycle facilities along Ala Moana Boulevard), the increased number of conflicts between these two modes trigger a significant impact.

Finding: Potentially significant

[3] This equates to roughly 3,872 daily crossings.

MITIGATION MEASURES

Mitigation recommendations to mitigate the traffic, bicycle and pedestrian impacts described in the TOD Alternative A are described in this section. Not all impacts can be fully mitigated, resulting in identified significant and unavoidable impacts at a limited number of specific locations.

SUMMARY OF RECOMMENDED TRANSPORTATION MITIGATIONS

Traffic Mitigations

Table 22 summarizes the potential traffic impacts, based on the findings of the analysis of the TOD Alternative A, and describes recommended mitigation measures.

Transit Mitigations

Impacts to transit capacity and operations resulting from the Project were found to be less than significant. Therefore, no transit mitigations are required.

Bicycle Mitigations

Table 23 on page 101 summarizes the significant, yet avoidable bicycle impacts for the Future Baseline Condition and TOD Alternative A with their corresponding mitigation measures.

Pedestrian Mitigations

Table 24 on page 102 summarizes the significant, yet avoidable pedestrian impacts for the Future Baseline Condition and TOD Alternative A with their corresponding mitigation measures.

Table 22 Motor Vehicle Traffic Mitigations

Impacted Locations	Proposed Motor Vehicle Mitigation			Impact Finding with Mitigation	
	Impact Finding	Potential Mitigation	Secondary Impact of Mitigation	Level of Significance with Mitigation	Recommendation
Ala Moana & South	LOS F under Future Baseline Condition. TOD Alternative A would increase V/C.	Increase allocation of green time per cycle to Ala Moana.	Increased delay to side-street motorists, bicyclists and pedestrians.	Intersection remains at LOS F due to side-street delay.	Trip reduction mitigation to achieve 9% reduction in PM Peak Hour Traffic Volume (below model-forecasted volumes).
Ala Moana & Cooke					
Ala Moana & Ward	LOS F under Future Baseline Condition. TOD Alternative A would increase V/C.	Restripe north/south approaches to eliminate split signal phases. Reduce length of east-leg pedestrian crossing.	On east-leg only: would require wider curb-to-curb width.	Intersection remains at LOS F due to side-street delay.	
Queen & Ward	LOS F under Future Baseline Condition. Identified as significant and unavoidable in 2009 Kaka`ako Mauka Plan SEIS.	N/A	N/A	N/A	N/A
Kapiolani & Ward	LOS F under Future Baseline Condition. Identified as significant and unavoidable in 2009 Kaka`ako Mauka Plan SEIS.	N/A	N/A	N/A	N/A

Table 23 Bicycle Mitigations

Impacted Corridors	Proposed Bicycle Mitigation			Impact Finding with Mitigation	
	Impact Finding	Mitigation	Secondary Impact	Bicycle Impact	Secondary Impact
Punchbowl Street	Potentially significant due to forecasted increase in bicycle volume and lack of bicycle capacity.	Restripe with bollard-protected bike lane.	N/A – bicycle lane can be accommodated with restriping.	Less than significant.	N/A
South Street		Restripe with bollard-protected bike lane.	Removal of on-street parking on one side.	Less than significant.	Less than significant – no reduction in traffic lane capacity.
Cooke Street		Restripe with 3 lanes and bike lanes	Removal of one motor vehicle travel lane.	Less than significant.	Less than significant – traffic LOS would remain acceptable.
Ward Avenue		Install bicycle lanes.	Removal of on-street parking.	Less than significant.	Less than significant – no reduction in traffic lane capacity.
Pensacola Street		Restripe with bike lane; study potential two-way conversion with 3 lanes and bike lanes	N/A – bicycle lane can be accommodated with restriping.	N/A	N/A
Piikoi Street*		Restripe with bollard-protected bike lane; study potential two-way conversion with 3 lanes and bike lanes	Bicycle lane can be accommodated with restriping. Potential impact from bollard.	N/A	N/A
Halekauwila Street		Construct cycle track or stripe bike lanes; cycle track alignment and design is contingent on the final design and location of HART guideway columns.	Removal of on-street parking.	N/A	N/A

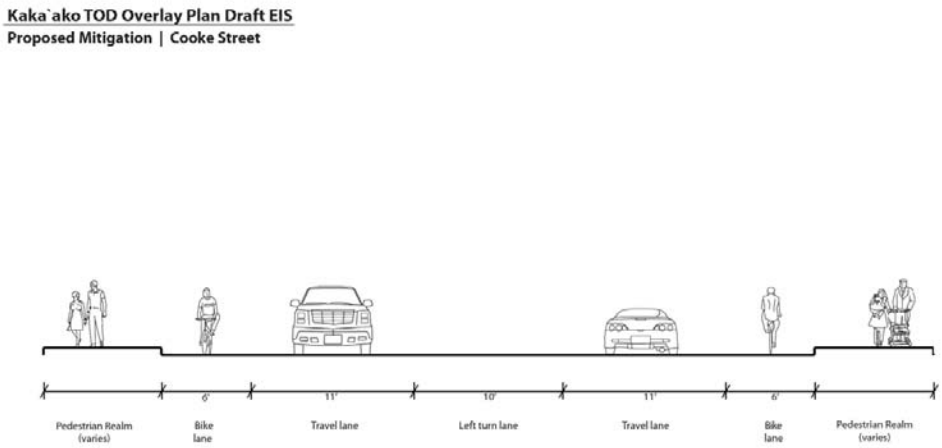
Table 24 Pedestrian Mitigations

Impacted Pedestrian Corridors (impact type)	Proposed Pedestrian Mitigation			Impact Finding With Mitigation	
	Impact Finding	Mitigation	Secondary Impact	Pedestrian Impact	Secondary Impact
All corridors (long crossing distances)	Potentially significant	Construct curb extensions at all intersections with on-street parking and that have 24' curb-to-curb walk distances of minor streets or 26' curb-to-curb walk distances of major streets; Reduce intersection skew; Tighten intersection geometry; Construct pedestrian refuge islands (Each mitigation measure requires further study)	Curb extensions may remove a small amount of on-street parking and reduce shy distance from parking and the curb face.	Less than significant with mitigation	Less than significant
All corridors (capacity issues due to change in pedestrian activity)	Potentially significant	Require redevelopment setbacks that ensure a minimum 15' pedestrian realm (sidewalk plus buffer including furniture zone and landscaping) regardless of existing pedestrian realm width. If the existing pedestrian realm is greater than 15', then there is no significant impact.	N/A	Less than significant with mitigation	Less than significant
Central Kaka`ako industrial streets	Potentially significant	Reconstruct streets as shared industrial streets while maintaining delivery and parking storage functions  Example of a shared street	Potential impact to parking supply.	Less than significant with mitigation	Less than significant
Ala Moana Boulevard (signal timing improvements)	Potentially significant	Reduce Ala Moana signal cycle lengths to 120 seconds and couple with other signal optimization features; this will create more lane capacity (from 800vph to 1200vph)	Reduces minor street signal phase by 20 seconds. Potential impact to vehicle turn storage, including deliveries.	Less than significant with mitigation	Less than significant
Ala Moana Boulevard (pedestrian improvements)	Potentially significant.	Construct makai side shared use path	Potential impact to pedestrians on makai side.	Less than significant with mitigation	Less than significant if adequate pedestrian path is maintained

MITIGATION CROSS SECTIONS

Figures 48 to 55 illustrate the proposed changes to streets with recommended mitigation measures for the TOD Alternative A. Streets with varying sidewalk widths are illustrated with ranges. All cross sections are conceptual and would require further engineering study prior to implementation.

Figure 48 Proposed Bicycle Mitigation: Cooke Street (Cross-section Drawing)



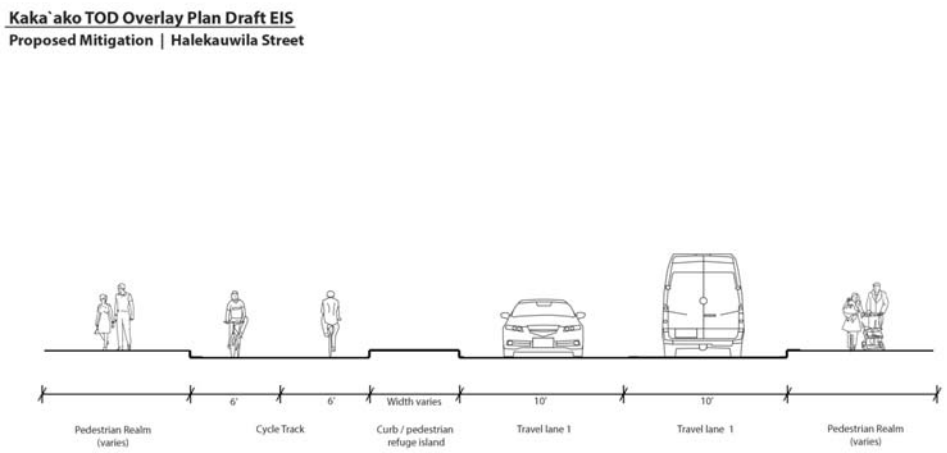


Figure 49 Proposed Bicycle Mitigation: Halekauwila Street (Cross-section Drawing)

Note: Cycle track alignment and design may depend on the final design and location of HART guideway columns. If a center-running guideway design is selected along Halekauwila, the colum widths could maintain the cycle track separation and maintain a large amount of on-street parking.

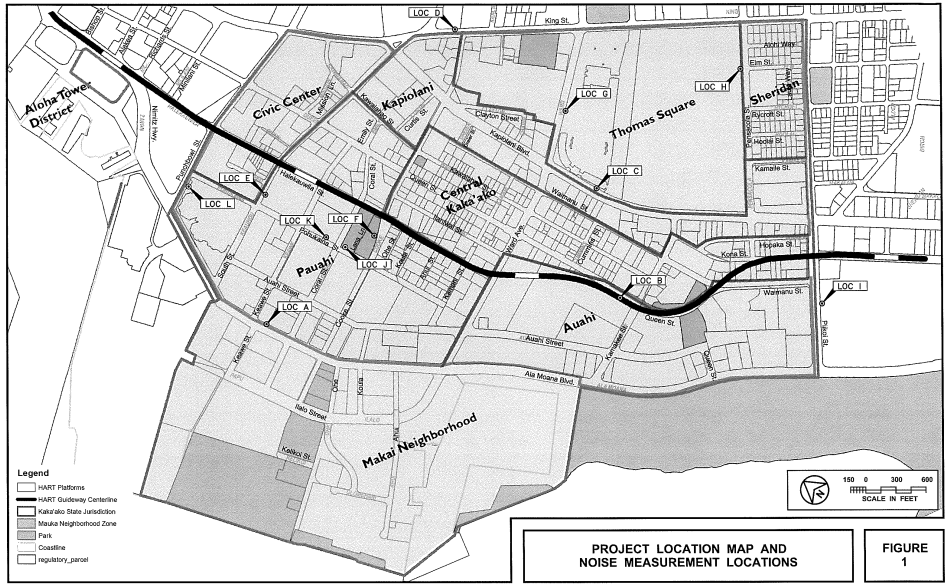
CHAPTER I. SUMMARY



The existing and future traffic noise levels in the vicinity of the proposed Transit-Oriented Development (TOD) project for the Kaka`ako Community Development District (KCDD) and Aloha Tower Special District (ATSD) were evaluated for their potential impacts and their relationship to current FHA/HUD (Federal Housing Administration/Housing and Urban Development) noise standards. The traffic noise level increases, including the contributions of noise from the elevated transit (rail) system in the study area (see Figure 1) were calculated. No significant traffic noise impacts are predicted to occur as a result of the TOD plan by CY 2035.

Along the major roadways in the study area (King Street, Kapiolani Boulevard, Ala Moana Boulevard, Nimitz Highway, Ward Avenue, Piikoi Street, Cooke Street, and South Street), traffic noise levels are expected to remain above the 65 DNL (Day-Night Sound Level) FHA/HUD standard at 50 foot distance from the roadways' centerlines in CY 2035. Increases in future traffic noise levels associated with the TOD plan are typically less than 1.0 DNL. In a few cases (Ala Moana Boulevard, Kamakee Street, Cooke Street, and Piikoi Street) project traffic will add between 1.I and 3.4 additional DNL units of noise to those streets. Overall, the traffic noise level increases resulting from project generated traffic are not considered to be significant. The predicted increases in traffic noise levels are not expected to generate adverse noise impacts by CY 2035.

The planned elevated transit (rail) system will cross through the center of the study area where existing and future traffic noise levels are relatively low. The rail system is expected to reduce the increases in future project and non-project motor vehicle traffic noise levels, but will add a corridor of relatively high noise levels near the center of the study area. A buffer distance of approximately 192 to 200 feet from the center of the rail system will probably be required to minimize the risks of exceeding the 65 DNL noise standard as a result of the combined contributions from both rail and motor vehicle traffic noise.

Unavoidable, but temporary, noise impacts may occur during construction activities, and particularly during the excavation and potential pile driving activities within the study area. Because construction activities are predicted to be audible within the study area and at adjoining properties, the quality of the acoustic environment may be degraded to unacceptable levels during periods of construction. Mitigation measures to reduce construction noise to inaudible levels will not be practical in all cases, but the use of quiet equipment and the adherence to Hawaii State Department of Health noise permit requirements are recommended as standard mitigation measures.

Because of the presence of low, mid-rise, and high-rise buildings throughout the study area and the potential for damage to these buildings from vibration during potential pile driving operations, vibration monitoring is recommended during close-in

PROJECT LOCATION MAP AND NOISE MEASUREMENT LOCATIONS | **FIGURE 1**

pile driving operations where vibration levels are expected to exceed 0.2 inches/second. In addition, it is expected that the design and construction methods for new buildings in the study area will be optimized to minimize risks of damage to adjacent structures from settling or heaving. A vibration limit of 2.0 inches/second should not be exceeded at any of the adjacent buildings, and modifications to a project's plans prior to design and construction are recommended if these limits are expected to be exceeded.

CHAPTER II. PURPOSE

The primary objective of this study was to describe the existing and future traffic noise environment in the environs of the proposed Transit-Oriented Development (TOD) Project within the Kaka`ako Community Development District (KCDD) and the Aloha Tower Special District (ATSD) on the island of Oahu. Traffic forecasts for both the Baseline Condition and for the TOD Alternative A in 2035 were used. Traffic noise level increases and impacts associated with the TOD Alternative A (referred to as Alternative A) were to be determined within the project area as well as along the public roadways which are expected to service the project area. A specific objective was to determine future traffic noise level increases associated with both project and non-project traffic, and the potential noise impacts associated with these increases.

The potential noise impacts from TOD Alternative B were not examined in depth, but are expected to be similar to or slightly less than the potential noise impacts from TOD Alternative A. This is because the density of TOD Alternative B is expected to be 90 percent of the density of TOD Alternative A. Therefore, the potential noise impacts described in this report represent the worst case situation anticipated in 2035.

Evaluation of impacts from short term construction noise and vibration in the project environs were also included as noise study objectives. Specifically, the potential risks of structural damage to adjacent buildings from pile driving operations on the project site were included in the noise and vibration impact assessment. Recommendations for minimizing identified noise and vibration impacts were also to be provided as required.

CHAPTER III. NOISE DESCRIPTORS AND THEIR RELATIONSHIP TO LAND USE COMPATIBILITY

The noise descriptor currently used by federal agencies (such as FHA/HUD) to assess environmental noise is the Day-Night Average Sound Level (Ldn or DNL). This descriptor incorporates a 24-hour average of instantaneous A-Weighted Sound Levels as read on a standard Sound Level Meter. By definition, the minimum averaging period for the DNL descriptor is 24 hours. Additionally, sound levels which occur during the nighttime hours of 10:00 PM to 7:00 AM are increased by 10 decibels (dB) prior to computing the 24-hour average by the DNL descriptor. A more complete list of noise descriptors is provided in Appendix B to this report.

Table 1, derived from Reference 1, presents current federal noise standards and acceptability criteria for residential land uses. Land use compatibility guidelines for various levels of environmental noise as measured by the DNL descriptor system are shown in Figure 2. As a general rule, noise levels of 55 DNL or less occur in rural areas, or in areas which are removed from high volume roadways. In urbanized areas which are shielded from high volume streets, DNL levels generally range from 55 to 65 DNL, and are usually controlled by motor vehicle traffic noise. Residences which front major roadways are generally exposed to levels of 65 DNL, and as high as 75 DNL when the roadway is a high speed freeway. In the project area, traffic noise levels associated with Nimitz Highway, Ala Moana Boulevard, Kapiolani Boulevard, King Street, Ward Avenue, Piikoi Street, Punchbowl Street, Pensacola Street, South Street, and Cooke Street are typically greater than 65 DNL along their Rights-of-Way due to the large volumes of traffic on those major thoroughfares.

For purposes of determining noise acceptability for funding assistance from federal agencies (FHA/HUD and VA), an exterior noise level of 65 DNL or less is considered acceptable for noise sensitive properties. This standard is applied nationally (Reference 2), including Hawaii. Because of our open-living conditions, the predominant use of naturally ventilated dwellings, and the relatively low exterior-to-interior sound attenuation afforded by these naturally ventilated structures, an exterior noise level of 65 DNL does not eliminate all risks of noise impacts. Because of these factors, and as recommended in Reference 3, a lower level of 55 DNL is considered to be the "Unconditionally Acceptable" (or "Near-Zero Risk") level of exterior noise. However, after considering the cost and feasibility of applying the lower level of 55 DNL, government agencies such as FHA/HUD and VA have selected 65 DNL as a more appropriate regulatory standard.

For commercial, industrial, and other non-noise sensitive land uses, exterior noise levels as high as 75 DNL are generally considered acceptable. Exceptions to this occur when naturally ventilated office and other commercial establishments are exposed to exterior levels which exceed 65 DNL.

On the island of Oahu, the State Department of Health (DOH) regulates noise from construction activities through the issuance of permits for allowing excessive

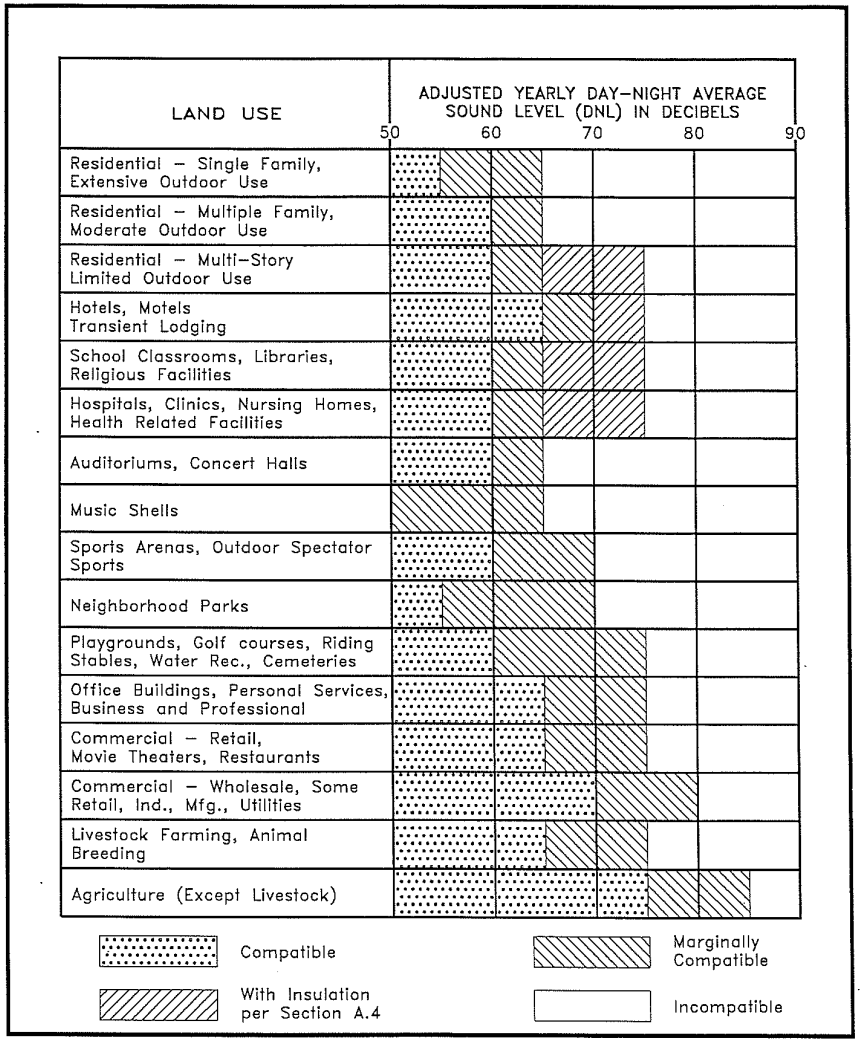


TABLE 1

EXTERIOR NOISE EXPOSURE CLASSIFICATION (RESIDENTIAL LAND USE)

NOISE EXPOSURE CLASS	DAY–NIGHT SOUND LEVEL	EQUIVALENT SOUND LEVEL	FEDERAL (1) STANDARD
Minimal Exposure	Not Exceeding 55 DNL	Not Exceeding 55 Leq	Unconditionally Acceptable
Moderate Exposure	Above 55 DNL But Not Above 65 DNL	Above 55 Leq But Not Above 65 Leq	Acceptable(2)
Significant Exposure	Above 65 DNL But Not Above 75 DNL	Above 65 Leq But Not Above 75 Leq	Normally Unacceptable
Severe Exposure	Above 75 DNL	Above 75 Leq	Unacceptable

Notes: (1) Federal Housing Administration, Veterans Administration, Department of Defense, and Department of Transportation.

(2) FHWA uses the Leq instead of the Ldn descriptor. For planning purposes, both are equivalent if: (a) heavy trucks do not exceed 10 percent of total traffic flow in vehicles per 24 hours, and (b) traffic between 10:00 PM and 7:00 AM does not exceed 15 percent of average daily traffic flow in vehicles per 24 hours. The noise mitigation threshold used by FHWA for residences is 67 Leq.

LAND USE COMPATIBILITY WITH YEARLY AVERAGE DAY–NIGHT AVERAGE SOUND LEVEL (DNL) AT A SITE FOR BUILDINGS AS COMMONLY CONSTRUCTED.
(Source: American National Standards Institute S12.9–1998/Part 5)

FIGURE 2

noise during limited time periods. State DOH noise regulations are expressed in maximum allowable property line noise limits rather than DNL (see Reference 4). Although they are not directly comparable to noise criteria expressed in DNL, State DOH noise limits for residential, commercial, and industrial lands equate to approximately 55, 60, and 76 DNL, respectively. The State of Hawaii Hawaii Community Development Authority (HCDA) has established property line noise limits for the KCDD depending on the emphasis placed by their multiuse zoning districts. Although they are not directly comparable to noise criteria expressed in DNL, HCDA noise limits for residential, commercial, and waterfront industrial lands equate to approximately 60, 60, and 70 DNL, respectively.

It should be noted that the noise compatibility guidelines and relationships to the DNL noise descriptor may not be applicable to impulsive noise sources such as pile drivers. The use of penalty factors (such as adding 10 dB to measured sound levels or the use of C-Weighting filters) have been proposed. However, the relationships between levels of impulsive noise sources and land use compatibility have not been as firmly established as have the relationships for non-impulsive sources. The State DOH limits for impulsive sounds which exceed 120 impulses in any 20 minute period are 10 dB above the limits for non-impulsive sounds. If impulsive sounds do not exceed 120 impulses in any 20 minute time period, there are no regulatory limits on their sound levels under the State DOH regulations.

CHAPTER IV. GENERAL STUDY METHODOLOGY

Existing traffic noise levels were measured at twelve locations (A through L) in the project environs to provide a basis for developing the project's traffic noise contributions along the roadways which will service the project area. The locations of the measurement sites are shown in Figure 1. Traffic noise measurements were performed between the end of 2012 through 2013. The results of the traffic noise measurements were compared with calculations of existing traffic noise levels to validate the computer model used. The traffic noise measurement results, and their comparisons with computer model predictions of existing traffic noise levels are summarized in Table 2.

Traffic noise calculations for the existing conditions as well as noise predictions for 2035 were performed using the Federal Highway Administration (FHWA) Traffic Noise Model (Reference 5). Traffic data entered into the noise prediction model were: roadway and receiver locations; hourly traffic volumes, average vehicle speeds; estimates of traffic mix; and "Pavement" propagation loss factor. The traffic data and forecasts for the project (Reference 6), plus the spot traffic counts obtained during the noise measurement periods were the primary sources of data inputs to the model. Appendix C summarizes the AM and PM peak hour traffic volumes for CY 2013 and 2035, which were used to model existing and future traffic noise along the streets in the study area. Year 2011 and 2012 traffic data along the roadways in the project environs from References 7 through 32 were used to model existing and future traffic noise levels along the roadways in the project environs. For existing and future traffic along the roadways in the project environs, the relationships between the 24-hour DNL and the AM or PM peak hour Leq(h)'s were derived from References 7 through 32 and were assumed to be as shown in Table 3. The Leq(h) to DNL conversion factors for the high volume roadways were obtained from calculations of traffic noise levels using the 24-hour traffic counts provided in References 7 through 32. Examples of the results of these calculations are shown in Figures 3 through 9.

Traffic noise calculations for both the existing and future conditions in the project environs were developed for ground level and elevated receptors. Traffic noise levels were also calculated for future conditions with and without the proposed project. The anticipated noise levels from the planned elevated light rail system were included in the forecasts of future noise levels in the project environs with and without the proposed KCDD/ATSD development plan. The forecasted changes in total (road traffic plus rail) noise levels over existing levels were calculated with and without the project, and noise impact risks evaluated. References 33 and 34 were used to develop the anticipated noise contributions from the elevated light rail system within the KCDD/ATSD study area. The relative contributions of non-project and project traffic to the total noise levels were also calculated, and an evaluation of possible traffic noise impacts was made.

Calculations of average exterior and interior noise levels from construction

activities were performed for typical naturally ventilated and air conditioned dwellings. Predicted noise levels were compared with existing background ambient noise levels, and the potential for noise impacts was assessed. Potential noise and vibration impacts from pile driving operations were also discussed, and mitigation measures recommended.

V. EXISTING ACOUSTICAL ENVIRONMENT

The existing background ambient noise levels within the project area are dependent upon receptor location relative to the high volume roadways, receptor elevation, and spatial relationships to fixed noise sources in the vicinity of the receptor. At ground level, traffic noise from streets within visual line of sight to the receptor will tend to control the residual background noise level. Because of the wide range (74 to 57 DNL) of traffic noise from the high to low volume streets in the project area, the residual background noise levels at ground level receptors also exhibit this wide range. At the higher elevations over the project area, the visual lines of sight to the more distant and high volume streets increase, so residual background noise levels due to traffic noise may be higher at the higher elevations than at the lower elevations. In addition, at the higher elevations, the visual lines of sight to rooftop air conditioning or ventilation equipment could cause total background noise levels to be higher at elevated receptor locations. This is the result of decreased noise shielding effects by existing buildings as the receptor elevations increase at a given location within the study area.

At receptor locations with visual lines of sight to the high volume roadways, the hourly variations in traffic noise levels will be similar to those shown in Figures 3 through 9. Receptors which are shielded from these high volume streets will experience similar variations in hourly traffic noise levels, but the overall levels will be much lower (by 8 to 16 dBA) than those shown in Figures 3 through 9. Residual background noise levels (or the noise levels during periods of no traffic flow on the closest roadway) are controlled by distant traffic, operating machinery, landscaping equipment, construction equipment, voices, and the natural sounds of birds and foliage moving with the wind. Residual daytime background noise levels are typically higher (by 5 to 15 dBA) than those during the nighttime and early morning hours, and can be as low as 42 to 45 dBA at locations removed from the major roadways. The project area's residual background noise levels are approximately midway between those of low density residential areas and the Waikiki area.

The results of the traffic and background ambient noise measurements are summarized in Table 2, with measurement locations identified in Figure 1. The measurement sites were typically located at street level, except at Location I, which was elevated at the second level of the shopping center's parking structure. As shown in Table 2, correlation between measured and predicted traffic noise levels was good. The traffic noise model's "Pavement" propagation loss factor was used to obtain the good correlation. Table 4 presents the calculations of existing traffic noise levels during the AM or PM peak traffic hour (whichever was the highest) at 50, 75, and 100 feet setback distances from the roadways' centerlines. Estimated distances to the roadways' 65, 70, and 75 DNL contours are shown in Table 5 for unobstructed line of sight conditions.

Motor vehicle traffic is the dominant noise source in the project area, and its

Notes:

(1) All setback distances are from the roadways' centerlines.
(2) See Tables 4 and 6 for traffic volume, speed, and mix assumptions.
(3) Setback distances are for ground level receptors.
(4) "Pavement" conditions assumed along all roadways.

volume, average speed, and vehicle mix determine which traffic corridors are in the "Significant Exposure, Normally Unacceptable" noise exposure category or greater than 65 DNL. Using the results shown in Table 5, the estimated locations of the existing 65 DNL contours are shown graphically in Figure 10, with the crosshatched areas representing potential traffic noise levels within the "Significant Exposure, Normally Unacceptable" noise exposure zone or greater than 65 DNL (see Table 1). Actual traffic noise levels within the crosshatched regions of Figure 10 could be less than 65 DNL if the receptor is shielded from the traffic lanes by intervening buildings or walls. They could also be higher than those shown in Figure 10 at receptor locations which receive traffic noise contributions from more than one roadway.

Using the results shown in Table 5 and Figure 10, the following conclusions were possible regarding existing traffic noise levels in the project area:

- The Aloha Tower District is essentially all within the "Significant Exposure, Normally Unacceptable" noise exposure zone due to traffic noise from Nimitz Highway.
- The Makai Neighborhood's "Significant Exposure, Normally Unacceptable" noise exposure zone is located along its mauka boundary, and controlled by traffic on Ala Moana Boulevard.
- The Civic Center Neighborhood's "Significant Exposure, Normally Unacceptable" noise exposure zones are located along its district boundaries at King, South, and Punchbowl Streets.
- The Pauahi Neighborhood's "Significant Exposure, Normally Unacceptable" noise exposure zones are located along its district boundaries at Ala Moana Boulevard and Ward Avenue, and to a lesser extent at Punchbowl, Cooke, and Coral Streets. A relatively large portion of the district is not within the 65 DNL noise exposure zone.
- The Kapiolani Neighborhood's "Significant Exposure, Normally Unacceptable" noise exposure zones represent 50.3 percent of the total land area within its district boundaries because of its orientation alongside Kapiolani Boulevard, King Street, Ward Avenue, Pensacola Street, and Piikoi Street.
- The Thomas Square Neighborhood's "Significant Exposure, Normally Unacceptable" noise exposure zones are located along King, Pensacola, and Cooke Streets and along Ward Avenue and Kapiolani Boulevard.
- The Central Kaka`ako Neighborhood's "Significant Exposure, Normally Unacceptable" noise exposure zones are located along Ward Avenue and Cooke, Pensacola, and Piikoi Streets.

PROJECT STUDY AREAS LOCATED WITHIN 65 DNL TRAFFIC NOISE EXPOSURE ZONES

FIGURE 10

- The Sheridan Neighborhood's "Significant Exposure, Normally Unacceptable" noise exposure zones are located along King, Pensacola, and Piikoi Streets.

- The Auahi Neighborhood's "Significant Exposure, Normally Unacceptable" noise exposure zones are located along Ala Moana Boulevard, Ward Avenue, and Piikoi Street.

CHAPTER VI. FUTURE NOISE ENVIRONMENT

Motor Vehicle Traffic Noise. Predictions of future traffic noise levels with and without the TOD Plan were made using the traffic volume assignments of Reference 6 for CY 2035. The future projections of project plus non-project traffic noise levels along the roadways which service the project area are shown in Table 6 for the AM or PM peak hour of traffic, under Alternative A. Table 7 presents the calculations of future traffic noise level changes along each roadway from 2013 to 2035 from non-project and project traffic. Table 5 presents the future setback distances to the 65, 70, and 75 DNL traffic noise contours under Alternative A for unobstructed line-of-site conditions.

Except for the section of Kamakee Street between Ala Moana Boulevard and Auahi Street, essentially no significant increases in traffic noise levels are expected in the project environs between CY 2011 and 2035 as a result of the project (see Table 7). Traffic noise level increases associated with the TOD Plan are predicted to be 1.3 DNL or less along all of the other street sections evaluated. Baseline traffic noise level increases from 2013 to 2035 not attributable to the TOD Plan are typically higher than those attributable to the TOD Plan (see Table 7). Figure 11 depicts the estimated locations of the 2035 traffic noise contours within the various neighborhoods of the KCDD. The anticipated increases in the "Significant Exposure, Normally Unacceptable" noise exposure zones are shown in Table 5 and can be seen visually by comparing Figures 10 and 11. It should be noted that the primary cause of the relatively large increases in the sizes of the "Significant Exposure, Normally Unacceptable" noise exposure zones from 2013 to 2035 is the projected increases in Baseline traffic volumes (except along Kamakee Street between Ala Moana Boulevard to Auahi Street). Also shown in Figure 11 are the locations of noise sensitive residential developments which are under construction or in the planning phases (Star-Advertiser, June 3, 2013).

The dominant traffic noise sources in the project area will continue to be traffic noise from Nimitz Highway, Ala Moana Boulevard, Kapiolani Boulevard, King Street, and Ward Avenue. Some sections of Piikoi, South, and Cooke Streets will also have future 65 DNL contour zones similar to the existing 65 DNL contour zones along Kapiolani Boulevard. As is the situation with existing receptors in Kaka`ako, the beneficial effects of shielding from existing or future buildings and walls will lower the predicted traffic noise levels and setback distances shown in Table 5, Table 6, and Figure 11 for future receptors.

Figure 11 also includes the locations of ground and high-rise receptors where existing and future traffic noise levels were calculated. At each labeled receptor, multiple receptor locations (indicated by three solid circles) at 50, 100, and 200 feet setback distance from the roadway centerline and at ground level, 50, 100, 150, 200, and 300 feet elevations were used to calculate existing, Future Baseline, and Future Alternative A traffic noise levels. At these receptor locations, the effects resulting from increased receptor setbacks and elevations, and from combining traffic noise

LOCATIONS OF ELEVATED RECEPTORS WHERE WIDE AREA TRAFFIC NOISE LEVELS WERE CALCULATED

FIGURE 11

contributions from multiple roadway sections were included in the calculations. Table 8 presents the results of these calculations of worst case traffic noise DNL values, which do not include the noise shielding effects from buildings or walls. In general, the DNL values shown in Table 8 may be higher than those shown in Tables 4 through 6 because of the additive contributions from multiple roadway segments at each receptor location. The values shown in Table 8 may also be higher than actual values because of the traffic noise reduction effects of shielding from buildings and walls. Along the high volume streets, however, the values shown in Table 8 should be consistent with the values shown in Tables 4 through 6. The results shown in Table 8 indicate very small changes in 2035 traffic noise levels associated with the TOD plan.

Elevated Fixed Guideway (Rail) Transit System Noise. The Honolulu Fixed Guideway Transit System is expected to cross through the Mauka Neighborhood Zone of the KCDD where shown in Figure 1 and subsequent report figures. The elevated guideway is expected to range from approximately 29 to 42 feet above ground level, be of concrete construction, have 3 feet high sidewalls for mitigation of transit system noise impacts at low and mid-rise receptors, and include wheel skirts for transit vehicles to increase the noise attenuation for elevated receptors. Information used to describe the future noise levels from transit vehicles within or slightly beyond the KCCD planning boundaries were obtained from References 33 and 34. The following summarizes the predicted transit system noise levels for 2030 using the information contained in Appendix A of Reference 34:

- At 700 Richards Street, rail noise levels were predicted to range from 67 DNL to 62 DNL or less without soundwalls or wheel skirts. With "current design", predicted rail noise levels ranged from 65 DNL to 62 DNL or less. The use of 3 feet high sidewalls did not seem to be included in the "current design".

- At 610 Cooke Street, rail noise levels were predicted to range from 71 DNL to 72 DNL without soundwalls or wheel skirts. With "current design", predicted rail noise levels ranged from 56 DNL to 62 DNL. The use of 3 feet high sidewalls seemed to be included in the "current design".

- At Mother Waldron Park, rail noise level was predicted to be 62 DNL without soundwalls or wheel skirts. With "current design", predicted rail noise level was 47 DNL. The use of 3 feet high sidewalls seemed to be included in the "current design". The location within the park was not indicated, but was estimated to be approximately 200 feet from the vertical plane through the rail centerline.

- At 860 Halekauwila Street, rail noise levels were predicted to range from 72 DNL to 62 DNL or less without soundwalls or wheel skirts. With "current design", predicted rail noise levels ranged from 57 DNL to 61 DNL or less. The use of 3 feet high sidewalls seemed to be included in the "current design".

- At Uraku Tower, rail noise levels were predicted to range from 63 DNL to 61 DNL or less without soundwalls or wheel skirts. With "current design", predicted rail noise levels ranged from 61 DNL to 60 DNL or less. The use of 3 feet high sidewalls did not seem to be included in the "current design".

No rail transit system noise level predictions were provided in References 33 or 34 for Halekauwila Place, which is currently under construction or for Kamakee Vista, 1133 Waimanu, and Koolani, which are existing high-rise condominiums located within 200 feet of the rail baseline. Another high-rise development (404 Ward; Star-Advertiser, June 3, 2013) is also planned along the rail transit route at the corner of Halekauwila Street and Ward Avenue. For the three existing condominiums listed above plus the existing 610 Cooke Street mid-rise apartments and the 860 Halekauwila high-rise plus Halekauwila Place (which is under construction), predictions of future traffic plus rail transit system noise levels were performed to describe the existing and future total noise levels at the multifamily dwelling units along the rail transit corridor. The locations of these dwelling units are shown in Figure 12. The results of the existing, Future Baseline, and Future Alternative A traffic plus rail transit system noise levels at ground level and elevated receptors are shown in Table 9.

The results shown in Table 9 indicate that a buffer distance of approximately 192 feet from the elevated guideway centerline will be required in order to minimize the influence of the rail transit system noise contributions on exceedances of the 65 DNL federal noise standard due to the combined contributions from both rail and motor vehicle traffic noise. At dwelling units located within 120 feet of the guideway centerline, the rail transit system can be the dominant noise source if mitigation measures are not incorporated into the rail transit system design. Without mitigation measures, the rail transit system noise levels are expected to be similar to motor vehicle traffic noise levels along King Street or Ala Moana Boulevard in 2035 under Alternative A.

CHAPTER VII. DISCUSSION OF PROJECT-RELATED NOISE AND VIBRATION IMPACTS AND POSSIBLE MITIGATION MEASURES

Traffic Noise. Noise impacts from project related traffic along the roadways which are expected to service the project area are not expected since traffic noise increases associated with project traffic are not significant. Future traffic noise impacts at future residential units within the mauka neighborhoods of KCDD can occur if these residential units are located in areas with traffic noise levels which exceed the 65 DNL FHA/HUD standard for noise sensitive properties. Traffic noise mitigation measures would be required in these situations, particularly if FHA/HUD participation is involved with these developments. In general, these areas where the risk of exceeding the 65 DNL FHA/HUD standard for noise sensitive properties is high occur along the major traffic corridors.

The planned 690 Pohukaina Project (on the mauka side of Pohukaina Street between Keawe and Coral Streets) is located in a relatively low noise level area in the Pauahi Neighborhood (see Figure 12). Predictions of future traffic noise levels for Baseline and Alternative A Scenarios on the 690 Pohukaina Project site at 50, 150, and 250 feet from the centerline of Pohukaina Street are shown in Table 10. These receptor locations are indicated as being 430, 330, and 230 feet, respectively, from the centerline of the rail transit system, and range from ground level to 700 feet above ground level. Based on the results shown in the seventh and eighth columns of Table 10, it was concluded that motor vehicle traffic noise levels are not expected to exceed the 65 DNL FHA/HUD standard for noise sensitive properties at the receptor locations shown in Figure 12 and Table 10.

The possible 404 Ward Project (on the Ewa side of Ward Avenue at Halekauwila Street) is located in a relatively high noise level area in the Central Kaka'ako Neighborhood (see Figure 12). Predictions of future traffic noise levels for Baseline and Alternative A Scenarios on the 404 Ward Project site at 50, 100, and 200 feet from the centerline of Halekauwila Street are shown in Table 10. These receptor locations are indicated as being 50, 100, and 200 feet from the centerline of the rail transit system, and range from ground level to 300 feet above ground level. Based on the results shown in the seventh and eighth columns of Table 10, it was concluded that motor vehicle traffic noise levels will probably exceed the 65 DNL FHA/HUD standard for noise sensitive properties at the receptor locations shown in Figure 12 and Table 10.

Elevated Transit (Rail) System Noise. By 2035, the elevated transit system which crosses through the middle of the TOD study area will probably have a general effect of reducing the future increases in road traffic noise levels in the study area, and increasing the future background noise levels along the transit system corridor. The added noise levels from the transit system along that corridor will need to be considered as an added noise source which could cause total noise levels at noise sensitive properties to exceed the 65 DNL FHA/HUD standard. Because the transit system corridor is located within the quieter areas of the TOD study area, the noise level contributions from the elevated rail system can cause total background noise levels to

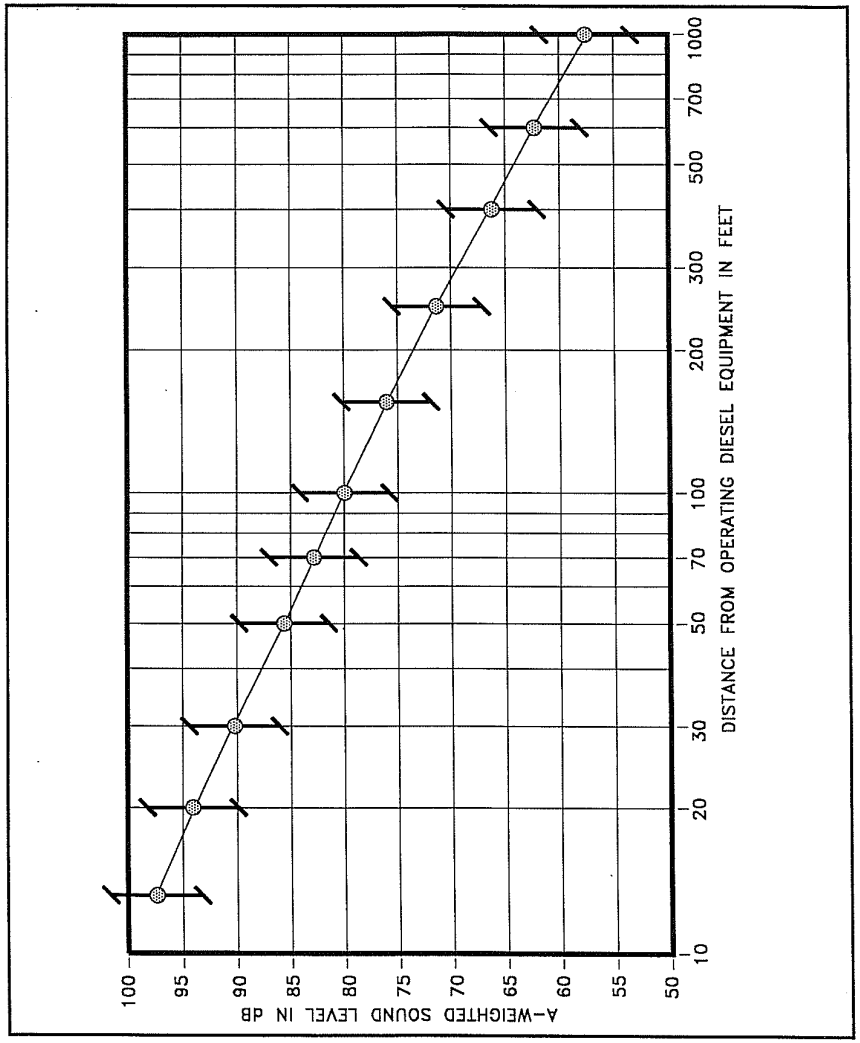
exceed the 65 DNL FHA/HUD standard, particularly where no rail noise mitigation measures are included within the transit system. For this reason, the location of noise sensitive developments at short setback distances from the rail system will probably trigger the need for the addition of sound attenuation measures at these developments.

For the elevated receptor locations shown in Figure 11 which are closest to the elevated rail corridor, the noise from the rail transit system could make significant contributions to the future total noise levels at the following locations: BNA, KHC, AHK, CQK, and QW. These five locations are all adjacent to the rail corridor. The noise from the rail transit system should not make significant contributions to the future total noise levels at the following locations: PQ, PP, KAQ, and PKP. All of these four locations are at least 250 feet from the rail centerline.

The elevated transit system is not expected to raise total (traffic plus rail) noise levels above the 65 DNL FHA/HUD standard at the 690 Pohukaina Project with or without rail noise mitigation (see Table 10). This is due to the large setback distance of the 690 Pohukaina Project from the rail alignment and the additional noise shielding effects from the Halekauwila Place building. The elevated transit system is expected to contribute to exceedances of the 65 DNL FHA/HUD standard at the 404 Ward Project with or without rail noise mitigation (see Table 10).



Noise Mitigation Measures. Noise mitigation measures for residential units located in areas with exterior noise levels which exceed the 65 DNL FHA/HUD noise standard will typically involve the use of closure and air conditioning. The use of sound attenuating walls or barriers will be of limited effectiveness, particularly where mid-rise and high-rise developments are involved. It should be noted that the erection of mid- and high-rise buildings adjacent to roadways or the elevated rail corridor will serve as partial sound barriers to properties which are located behind these buildings. However, as the density of these mid-and high-rise structures increase along a transportation corridor, their reflective surfaces will tend to increase the background noise levels along the transportation corridor. So, the use of closure and air conditioning will probably be the only available noise mitigation measure for noise sensitive developments located within the high noise zones.

General Construction Noise. Audible construction noise will probably be unavoidable during the entire project construction period of new developments within the study area. The total time period for construction will probably vary among the various projects, and it is anticipated that the actual work will be moving from one location on any project site to another during that period. Actual length of exposure to construction noise at any receptor location will probably be less than the total construction period for the entire project. Figure 13 depicts the range of noise levels of various types of construction equipment when measured at 50 FT distance from the equipment. Typical levels of exterior noise from construction activity (excluding pile driving activity) at various distances from the job site are shown in Figure 14. The

RANGES OF CONSTRUCTION EQUIPMENT NOISE LEVELS

FIGURE 13

ANTICIPATED RANGE OF CONSTRUCTION NOISE LEVELS VS. DISTANCE

FIGURE 14

impulsive noise levels of impact pile drivers are approximately 15 dB higher than the levels shown in Figure 14, while the intermittent noise levels of vibratory pile drivers are at the upper end of the noise level ranges depicted in the figure.

Figure 14 is useful for predicting exterior noise levels at short distances (within 100 FT) from the work when visual line of sight exists between the construction equipment and the receptor. Direct line-of-sight distances from the construction equipment to existing and future residential and commercial buildings will probably range from 20 FT to 1,300 FT, with corresponding average noise levels of 94 to 55 dBA (plus or minus 5 dBA). For receptors along a cross-street, the construction noise level vs. distance curve of Figure 14 should be reduced by approximately 8 dBA when the work is occurring at the intersection with the cross street, and should be reduced by 15 dBA when work is occurring at least 100 FT from the intersection (and the visual line-of-sight is blocked by intervening buildings). Typical levels of construction noise inside naturally ventilated and air conditioned structures are approximately 10 and 20 dB less, respectively, than the levels shown in Figure 14.

Adverse impacts from construction noise are not expected to be in the "public health and welfare" category due to the temporary nature of the work and due to the administrative controls available for regulation of construction noise. Instead, these impacts will probably be limited to the temporary degradation of the quality of the acoustic environment in the immediate vicinity of the construction site. Mitigation of construction noise to inaudible levels will not be practical in all cases due to the intensity of construction noise sources (80 to 90+ dB at 50 FT distance), and due to the exterior nature of the work (pile driving, grading and earth moving, trenching, concrete pouring, hammering, etc.). The use of properly muffled construction equipment should be required on the job site.

Peak airborne noise levels from pile diving may be as much as 15 dBA greater than noise levels shown in Figure 14 for non-impulsive (steady) construction noise sources. Although the pile driving can produce more intense noise levels, each pulse is of short individual duration (less than one second). Therefore, its impact on speech communication is not as severe as that of a steady source of the same noise level.

Severe noise impacts are not expected to occur inside air conditioned structures which are within 50 to 450+ FT of the project construction site. Inside naturally ventilated structures, interior noise levels (with windows or doors opened) are estimated to range between 55 to 76 dBA at 50 FT to 450+ FT distances from the construction site. Closure of all doors and windows facing the construction site would generally reduce interior noise levels by an additional 5 to 10 dBA.

The incorporation of State Department of Health construction noise limits and curfew times, which are applicable throughout the State of Hawaii (Reference 4), is another noise mitigation measure which is normally applied to construction activities. Figure 15 depicts the normally permitted hours of construction. Noisy construction

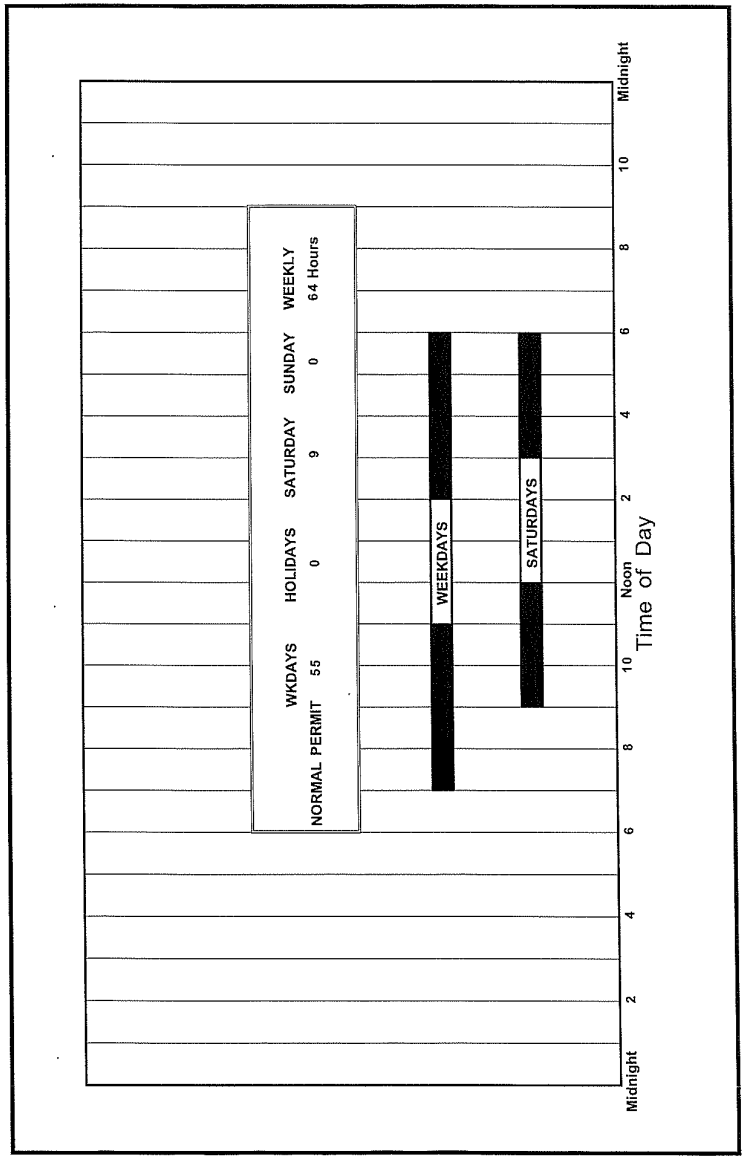


FIGURE 15

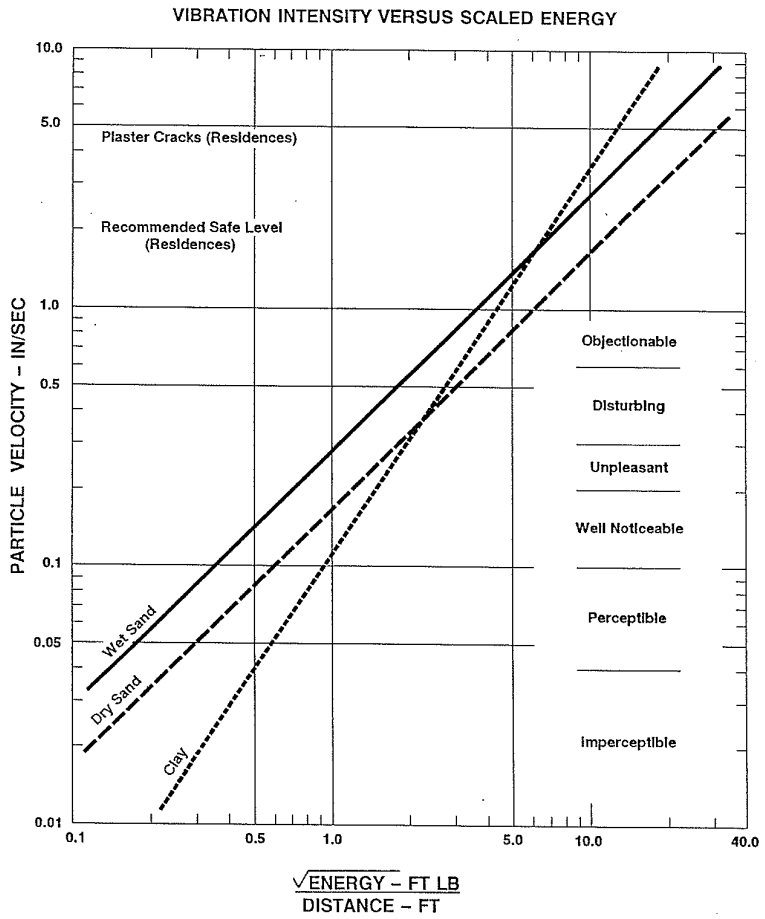
AVAILABLE WORK HOURS UNDER DOH PERMIT PROCEDURES FOR CONSTRUCTION NOISE

activities are not allowed on Sundays and holidays, during the early morning, and during the late evening and nighttime periods under the DOH permit procedures.

Vibration from Pile Driving. Pile driving may be necessary to implant piles into the ground at some construction sites. Impact driven concrete and sheet piles may both be used at a construction site. Induced ground vibrations from the pile driving operations have the potential to cause architectural and structural damage to nearby structures.

Ground vibrations generated during pile driving operations are generally described in terms of peak particle (or ground) velocity in units of inches/second. The human being is very sensitive to ground vibrations, which are perceptible at relatively low particle velocities of 0.01 to 0.04 inches/second. Damage to structures, however, occur at much higher levels of vibration as indicated in Table 11. The most commonly used damage criteria for structures is the 2.0 inches/second limit derived from work by the U.S. Bureau of Mines. A more conservative limit of 0.2 inches/second is also used, and is suggested for planning purposes on this project because of the repetitive nature of pile driving operations which can increase risks of damage due to fatiguing.

Based on measured vibration levels during pile driving operations under various soil conditions and at various distances, estimates of ground vibration levels vs. distance from the pile driver have been made for various soil conditions and for various energy ratings of the pile drivers. Figure 16, which was extracted from Reference 35, may be used to predict vibration levels for the soil conditions indicated. When coral layers must be penetrated, vibration levels can be expected to be higher than those shown in Figure 16, particularly if the adjacent structures are supported by the common coral layer. From Figure 16, and for wet sand soil conditions, the 0.2 inches/second vibration damage criteria will be exceeded at a scaled energy distance factor of approximately 0.7. The scaled energy distance factor is equal to the square root of the energy (in foot-pounds) per blow of the hammer divided by the distance (in feet) between the pile tip and the monitoring location. For a 22,400 foot-pound pile driver, a scaled energy distance of 0.7 equates to a required separation distance of 214 feet. Under clay soil conditions, and using the prediction procedures contained in Figure 16, a shorter separation distance of 100 feet is required to not exceed the 0.2 inches/second criteria when using a 22,400 foot-pound pile driver. It should be noted that 0.2 inches/second vibration levels were measured from a 22,400 foot-pound pile driver at even shorter separation distances of approximately 30 FT in sandy, layered soil (Reference 36). The measurement data reported in Reference 36 are significantly lower than the vibration levels predicted by the methodology of Reference 35.



As indicated above, predictions of peak ground vibration levels vs. scaled energy distance factor from the driven pile are not precise, with initial uncertainty factor for a given location in the order of 10:1. For this reason, it is standard practice to employ seismograph monitoring of ground vibrations during pile driving operations with a 3-axis geophone or accelerometer. If sheet pile drivers of approximately 2,500 foot-pounds or

TABLE 11

SUMMARY OF BUILDING DAMAGE CRITERIA

PEAK GROUND VELOCITY (mm/sec)	PEAK GROUND VELOCITY (in/sec)	COMMENT
193.04	7.6	Major damage to buildings (mean of data).
137.72	5.4	Minor damage to buildings (mean of data).
101.16	4.0	'Engineer structures' safe from damage.
50.8	2.0	Safe from damage limit (probability of damage <5%).
		No structural damage.
33.02	1.3	Threshold of risk of 'architectural' damage for houses.
25.4	1.0	No data showing damage to structures for vibration <1 in./sec.
15.24	0.6	No risk of 'architectural' damage to normal buildings.
10.16	0.4	Threshold of damage in older homes.
5.08	0.2	Statistically significant percentage of structures may experience minor damage (including earthquake, nuclear event, and blast data for old and new structures).
		No 'architectural' damage.
3.81	0.5 to 0.15	Upper limits for ruins and ancient monuments.
1.0	0.04	Vertical vibration clearly perceptible to humans.
0.32	0.01	Vertical vibration just perceptible to humans.

MAXIMUM VIBRATION INTENSITIES EXPECTED FROM PILE DRIVING

FIGURE 16

smaller ratings are anticipated to be used on the job site, the initial vibration predictions indicate that there is some risk of exceeding the 0.20 inches/second vibration damage criteria at 33 to 71 feet separation distances, and monitoring during pile driving operations is warranted if pile driving are planned at those distances from any existing structures.

The following preventive measures are recommended for implementation during the planning and design phases of the project:

- In addition to the normal planning and design concerns regarding potential damage due to settling and heaving during construction, consideration should also be given to risks of damage due to vibration from pile driving. A damage criteria of 0.2 inches/second should be used in conjunction with the vibration prediction method of Reference 35 to identify the potential damage risk distances to the driven piles.

- If predicted vibration levels from pile driving exceed 0.2 inches/second at a building, and predicted levels cannot be reduced by sizing of the pile driver, test piles should be driven and their vibrations monitored and recorded prior to completion of the foundation design. The monitoring of the test piles should be designed to measure the expected peak, 3-axis vibration levels at the building. The results of the monitoring should be used to define the empirical distance from the driven pile to the 0.2 inches/second damage risk location, and to evaluate the risks of structural damage to the adjacent structure during actual construction.

- If predicted vibration levels from pile driving exceed 2.0 inches/second at a building, the use of alternate types of piles or shoring should be considered for implementation during the design phase.

APPENDIX B

EXCERPTS FROM EPA'S ACOUSTIC TERMINOLOGY GUIDE

Descriptor Symbol Usage

The recommended symbols for the commonly used acoustic descriptors based on A-weighting are contained in Table I. As most acoustic criteria and standards used by EPA are derived from the A-weighted sound level, almost all descriptor symbol usage guidance is contained in Table I.

Since acoustic nomenclature includes weighting networks other than "A" and measurements other than pressure, an expansion of Table I was developed (Table II). The group adopted the ANSI descriptor-symbol scheme which is structured into three stages. The first stage indicates that the descriptor is a level (i.e., based upon the logarithm of a ratio), the second stage indicates the type of quantity (power, pressure, or sound exposure), and the third stage indicates the weighting network (A, B, C, D, E.....). If no weighting network is specified, "A" weighting is understood. Exceptions are the A-weighted sound level and the A-weighted peak sound level which require that the "A" be specified. For convenience in those situations in which an A-weighted descriptor is being compared to that of another weighting, the alternative column in Table II permits the inclusion of the "A". For example, a report on blast noise might wish to contrast the LCdn with the LAdn.

Although not included in the tables, it is also recommended that "Lpn" and "LepN" be used as symbols for perceived noise levels and effective perceived noise levels, respectively.

It is recommended that in their initial use within a report, such terms be written in full, rather than abbreviated. An example of preferred usage is as follows:

The A-weighted sound level (LA) was measured before and after the installation of acoustical treatment. The measured LA values were 85 and 75 dB respectively.

Descriptor Nomenclature

With regard to energy averaging over time, the term "average" should be discouraged in favor of the term "equivalent". Hence, Leq, is designated the "equivalent sound level". For Ld, Ln, and Ldn, "equivalent" need not be stated since the concept of day, night, or day-night averaging is by definition understood. Therefore, the designations are "day sound level", "night sound level", and "day-night sound level", respectively.

The peak sound level is the logarithmic ratio of peak sound pressure to a reference pressure and not the maximum root mean square pressure. While the latter is the maximum sound pressure level, it is often incorrectly labelled peak. In that sound level meters have "peak" settings, this distinction is most important.

"Background ambient" should be used in lieu of "background", "ambient", "residual", or "indigenous" to describe the level characteristics of the general background noise due to the contribution of many unidentifiable noise sources near and far.

With regard to units, it is recommended that the unit decibel (abbreviated dB) be used without modification. Hence, DBA, PNdB, and EPNdB are not to be used. Examples of this preferred usage are: the Perceived Noise Level (Lpn was found to be 75 dB. Lpn = 75 dB). This decision was based upon the recommendation of the National Bureau of Standards, and the policies of ANSI and the Acoustical Society of America, all of which disallow any modification of bel except for prefixes indicating its multiples or submultiples (e.g., deci).

Noise Impact

In discussing noise impact, it is recommended that "Level Weighted Population" (LWP) replace "Equivalent Noise Impact" (ENI). The term "Relative Change of Impact" (RCI) shall be used for comparing the relative differences in LWP between two alternatives.

Further, when appropriate, "Noise Impact Index" (NII) and "Population Weighed Loss of Hearing" (PHL) shall be used consistent with CHABA Working Group 69 Report Guidelines for Preparing Environmental Impact Statements (1977).

1.0 SUMMARY

The Hawaii Community Development Authority is proposing the Kaka'ako Transit-Oriented Development Overlay Plan for the Kaka'ako Community Development District on the island of Oahu. The proposed Plan will overlay (supplement) the existing rules governing development in the Kaka'ako District. The purpose of the proposed Plan is to maximize development by promoting smart growth principles, multi-modal transportation and walkability in the affected area. The proposed Plan extends through the year 2035 and is expected to result in an increase in residential development and a decrease in non-residential space. This study examines the potential short- and long-term air quality impacts that could occur as a result of the implementation of the proposed Plan and suggests mitigation measures to reduce any potential air quality impacts where possible and appropriate.

Both federal and state standards have been established to maintain ambient air quality. At the present time, seven parameters are regulated including: particulate matter, sulfur dioxide, hydrogen sulfide, nitrogen dioxide, carbon monoxide, ozone and lead. Hawaii air quality standards are comparable to the national standards except those for nitrogen dioxide and carbon monoxide which are more stringent than the national standards.

Regional and local climate together with the amount and type of human activity generally dictate the air quality of a given location. The climate of the Kaka'ako area is very much affected by its leeward and coastal situation. Winds are predominantly trade winds from the east northeast except for occasional periods when kona storms may generate strong winds from the south or when

the trade winds are weak and landbreeze-seabreeze circulations may develop. Wind speeds typically vary between about 5 and 15 miles per hour providing relatively good ventilation much of the time. Temperatures in leeward areas of Oahu are generally very moderate with average daily temperatures ranging from about 70°F to 84°F. The extreme minimum temperature recorded at Honolulu Airport is 54°F, while the extreme maximum temperature is 95°F. This area of Oahu is one of the drier locations in the state with rainfall often highly variable from one year to the next. Monthly rainfall has been measured to vary from as little as a trace to as much as 10 inches. Average annual rainfall amounts to about 24 inches with summer months being the driest.

The present air quality of the project area appears to be reasonably good based on nearby air quality monitoring data. Air quality data from the nearest monitoring stations operated by the Hawaii Department of Health suggest that all national air quality standards are currently being met, although occasional exceedances of the more stringent state standards for carbon monoxide may occur near congested roadway intersections. Episodes of volcanic haze sometimes reduce visibility, but even during these periods, air pollution concentrations generally meet current air quality standards.

If the proposed Plan is given the necessary approvals to proceed, there could be some short- and/or long-term impacts on air quality that may occur either directly or indirectly as a consequence of Plan implementation. Short-term impacts from fugitive dust could occur during the construction of additional residential housing units. To a lesser extent, exhaust emissions from stationary and mobile construction equipment, from the minor disruption of

traffic, and from workers' vehicles may also affect air quality during periods of construction. State air pollution control regulations require that there be no visible fugitive dust emissions at the property line. Hence, effective dust control measures should be implemented to ensure compliance with state regulations. Fugitive dust emissions can be controlled to a large extent by watering of active work areas, using wind screens, keeping adjacent paved roads clean, and by covering of open-bodied trucks. Other dust control measures to consider include limiting the area that is disturbed at any given time and/or mulching or chemically stabilizing inactive areas that have been worked. Paving and landscaping of project areas early in the construction schedule will also reduce dust emissions. Exhaust emissions can be mitigated by moving construction equipment and workers to and from the project site during off-peak traffic hours.

To assess the potential long-term impact of emissions from motor vehicle traffic operating on roadways in the study area after implementing the Plan through the year 2035, a computerized air quality modeling study was undertaken. The air quality modeling study estimated current worst-case concentrations of carbon monoxide at roadway intersections in the project vicinity and predicted future levels both with and without the proposed Plan. During worst-case conditions, model results indicated that present 1-hour and 8-hour worst-case carbon monoxide concentrations are well within both the state and the national ambient air quality standards. In the year 2035 without the Plan, worst-case carbon monoxide concentrations were predicted to generally decrease (improve) by about 10 to 20 percent. With the Plan in the year 2035, estimated worst-case carbon monoxide concentrations indicated only minimal or no impact compared to the without Plan case. Concentrations would remain well within

standards. Due to the negligible impact the proposed Plan is expected to have, implementing mitigation measures for long-term traffic-related air quality impacts is unnecessary and unwarranted.

2.0 INTRODUCTION

The Hawaii Community Development Authority (HCDA)is proposing the Kaka'ako Transit-Oriented Development (TOD) Overlay Plan within the Kaka'ako Community Development District (KCDD) on the island of Oahu (see Figure 1 for project location). The proposed TOD Plan will serve as an overlay on the existing rules governing development in the district, meaning that the existing rules remain in force and any proposed TOD development will be required to comply with the proposed TOD Plan. The implementation of the TOD Plan is intended to maximize development in the district by promoting the use of smart growth principles, multi-modal transportation and walkability. The proposed TOD Plan includes the 601.6-acre KCDD as well as the nearby 3.4-acre Aloha Tower Special District. The KCDD is bounded by King Street on the north, Piikoi Street and Ala Moana Regional Park on the east, Punchbowl Street and Pier 1 on the west, and the Pacific Ocean on the south. The Aloha Tower Special District is located on the ocean side of Ala Moana Boulevard and is bounded by Richard Street, Bishop Street and Aloha Tower Drive. The proposed TOD Plan would potentially accommodate an additional 14 million square feet of residential development, as compared to future baseline conditions, and it would reduce the amount of non-residential space accommodated by about two million square feet. The planning horizon for the TOD Overlay Plan is 2035.

The purpose of this study is to describe existing air quality in the project area and to assess the potential short- and long-term direct and indirect air quality impacts that could result from implementation of the proposed TOD Overlay Plan. Measures to mitigate project impacts are suggested where possible and appropriate.

3.0 AMBIENT AIR QUALITY STANDARDS

Ambient concentrations of air pollution are regulated by both national and state ambient air quality standards (AAQS). National AAQS are specified in Section 40, Part 50 of the Code of Federal Regulations (CFR), while State of Hawaii AAQS are defined in Chapter 11-59 of the Hawaii Administrative Rules. Table 1 summarizes both the national and the state AAQS that are specified in the cited documents. As indicated in the table, national and state AAQS have been established for particulate matter, sulfur dioxide, nitrogen dioxide, carbon monoxide, ozone and lead. The state has also set a standard for hydrogen sulfide. National AAQS are stated in terms of both primary and secondary standards for most of the regulated air pollutants. National primary standards are designed to protect the public health with an "adequate margin of safety". National secondary standards, on the other hand, define levels of air quality necessary to protect the public welfare from "any known or anticipated adverse effects of a pollutant". Secondary public welfare impacts may include such effects as decreased visibility, diminished comfort levels, or other potential injury to the natural or man-made environment, e.g., soiling of materials, damage to vegetation or other economic damage. In contrast to the national AAQS, Hawaii State AAQS are given in terms of a single standard that is designed "to

protect public health and welfare and to prevent the significant deterioration of air quality".

Each of the regulated air pollutants has the potential to create or exacerbate some form of adverse health effect or to produce environmental degradation when present in sufficiently high concentration for prolonged periods of time. The AAQS specify a maximum allowable concentration for a given air pollutant for one or more averaging times to prevent harmful effects. Averaging times vary from one hour to one year depending on the pollutant and type of exposure necessary to cause adverse effects. In the case of the short-term (i.e., 1- to 24-hour) AAQS, both national and state standards allow a specified number of exceedances each year.

The Hawaii AAQS are in some cases considerably more stringent than the comparable national AAQS. In particular, the Hawaii 1-hour AAQS for carbon monoxide is four times more stringent than the comparable national limit.

The national AAQS are reviewed periodically, and multiple revisions have occurred over the past 30 years. In general, the national AAQS have become more stringent with the passage of time and as more information and evidence become available concerning the detrimental effects of air pollution. In particular, national AAQS for sulfur dioxide and for nitrogen dioxide have been revised recently to include one-hour averaging periods. This is generally considered a move to make the standards for these air pollutants more stringent. Changes to the Hawaii AAQS over the past several years have tended to follow revisions to

the national AAQS, making several of the Hawaii AAQS the same as the national AAQS.

4.0 REGIONAL AND LOCAL CLIMATOLOGY

Regional and local climatology significantly affects the air quality of a given location. Wind, temperature, atmospheric turbulence, mixing height and rainfall all influence air quality. Although the climate of Hawaii is relatively moderate throughout most of the state, significant differences in these parameters may occur from one location to another. Most differences in regional and local climates within the state are caused by the mountainous topography.

Hawaii lies well within the belt of northeasterly trade winds generated by the semi-permanent Pacific high pressure cell to the north and east. On the island of Oahu, the Koolau and Waianae Mountain Ranges are oriented almost perpendicular to the trade winds, which accounts for much of the variation in the local climatology of the island. The site of the proposed project is located in the leeward area of the Koolau Mountains.

Wind frequency data for Honolulu International Airport (HIA), which is located about 10 miles to the east of the project site, are given in Table 2. These data can be expected to be reasonably representative of the project area. Wind frequency for HIA show that the annual prevailing wind direction for this area of Oahu is east northeast. On an annual basis, 34.7 percent of the time the wind is from this direction, and more than 70 percent of the time the wind is in the northeast quadrant. Winds from the south are

infrequent occurring only a few days during the year and mostly in winter in association with kona storms. Wind speeds average about 10 knots (12 mph) and mostly vary between about 5 and 15 knots (6 and 17 mph).

Air pollution emissions from motor vehicles, the formation of photochemical smog and smoke plume rise all depend in part on air temperature. Colder temperatures tend to result in higher emissions of contaminants from automobiles but lower concentrations of photochemical smog and ground-level concentrations of air pollution from elevated plumes. In Hawaii, the annual and daily variations of temperature depend to a large degree on elevation above sea level, distance inland and exposure to the trade winds. Average temperatures at locations near sea level generally are warmer than those at higher elevations. Areas exposed to the trade winds tend to have the least temperature variation, while inland and leeward areas often have the most. Based on more than 25 years of data collected at Honolulu International Airport, average annual daily minimum and maximum temperatures in the project area are about 70^{o}F and 84^{o}F, respectively [1]. The extreme minimum temperature on record at the airport is 54^{o}F, and the extreme maximum is 95^{o}F.

Small scale, random motions in the atmosphere (turbulence) cause air pollutants to be dispersed as a function of distance or time from the point of emission. Turbulence is caused by both mechanical and thermal forces in the atmosphere. It is oftentimes measured and described in terms of Pasquill-Gifford stability class. Stability class 1 is the most turbulent and class 6 the least. Thus, air pollution dissipates the best during stability class 1 conditions and the worst when stability class 6 prevails.

In the project area, stability class 5 is probably the highest stability class that occurs, developing during clear, calm nighttime or early morning hours when temperature inversions form due to radiational cooling. Stability classes 1 through 4 occur during the daytime, depending mainly on the amount of cloud cover and incoming solar radiation and the onset and extent of the sea breeze.

Mixing height is defined as the height above the surface through which relatively vigorous vertical mixing occurs. Low mixing heights can result in high ground-level air pollution concentrations because contaminants emitted from or near the surface can become trapped within the mixing layer. In Hawaii, minimum mixing heights tend to be high because of mechanical mixing caused by the trade winds and because of the temperature moderating effect of the surrounding ocean. Low mixing heights may sometimes occur, however, at inland locations and even at times along coastal areas early in the morning following a clear, cool, windless night. Coastal areas also may experience low mixing levels during sea breeze conditions when cooler ocean air rushes in over warmer land. Mixing heights in Hawaii typically are above 3000 feet (1000 meters).

Rainfall can have a beneficial effect on the air quality of an area in that it helps to suppress fugitive dust emissions, and it also may "washout" gaseous contaminants that are water-soluble. Rainfall in Hawaii is highly variable depending on elevation and on location with respect to the trade wind. The Kaka’ako area is one of the drier areas on Oahu due to its leeward and near sea level location. Average annual rainfall measured at nearby downtown Honolulu amounts to about 24 inches [2]. Most of the

rainfall usually occurs during the winter months. Monthly rainfall may vary from as little as a trace to more than 10 inches.

5.0 PRESENT AIR QUALITY

Present air quality in the project area is mostly affected by air pollutants from motor vehicles due to the urban situation. Table 3 presents an air pollutant emission summary for the island of Oahu for calendar year 1993. These are the most recent data available. The emission rates shown in the table pertain to manmade emissions only, i.e., emissions from natural sources are not included. As suggested in the table, much of the particulate emissions on Oahu originate from area sources, such as the mineral products industry and agriculture. Sulfur oxides are emitted almost exclusively by point sources, such as power plants and refineries. Nitrogen oxides emissions emanate predominantly from industrial point sources, although area sources (mostly motor vehicle traffic) also contribute a significant share. The majority of carbon monoxide emissions occur from area sources (motor vehicle traffic), while hydrocarbons are emitted mainly from point sources. Based on previous emission inventories that have been reported for Oahu, emissions of particulate and nitrogen oxides may have increased during the last several years, while emissions of sulfur oxides, carbon monoxide and hydrocarbons probably have declined.

Natural sources of air pollution emissions that could affect the project area at times but cannot be quantified very accurately include the ocean (sea spray), plants (aero-allergens), wind-blown dust, and perhaps distant volcanoes on the island of

Hawaii. When the persistent trade winds subside, volcanic haze (vog) originating from Kilauea Volcano on Hawaii Island sometimes affects the whole of Oahu. Kilauea Volcano has been erupting continuously for more than 25 years. The vog consists primarily of very fine particulate matter.

The State Department of Health operates a network of air quality monitoring stations at various locations on Oahu. Each station, however, typically does not monitor the full complement of air quality parameters. Table 4 shows annual summaries of air quality measurements that were made nearest to the project area for several of the regulated air pollutants for the period 2007 through 2011. These are the most recent data that are currently available.

During the 2007-2011 period, sulfur dioxide was monitored by the State Department of Health at an air quality station located at nearby downtown Honolulu. Concentrations monitored were consistently low compared to the standards. Annual second-highest 3-hour concentrations (which are most relevant to the air quality standards) ranged from 0.008 to 0.021 parts per million (ppm), while the annual second-highest 24-hour concentrations ranged from 0.002 to 0.005 ppm. Annual average concentrations were only about 0.001 ppm. There were no exceedances of the state/national 3-hour or 24-hour AAQS for sulfur dioxide during the 5-year period. It should be noted that the national AAQS for sulfur dioxide were revised during 2010, and data pertaining to the revised standards were only reported for 2011 (and are not shown in Table 4). Based on the information available, exceedance of the new 1-hour national AAQS for sulfur dioxide within the study area is very unlikely.

Particulate matter less than 2.5 microns in diameter (PM-2.5) is also measured at the downtown Honolulu monitoring station. Annual highest 24-hour PM-2.5 concentrations ranged from 9 to 50 micrograms per cubic meter ($\mu g/m^3$) between 2007 and 2011. The highest values were generally due to either fireworks on New Year's Eve or bad vog days. Only one exceedance of the 24-hour concentration limit was exceeded during this five-year period and that was due to New Year's Eve fireworks. Average annual concentrations ranged from 3.9 to 4.8 $\mu g/m^3$, which were within the state and national AAQS.

Carbon monoxide measurements were obtained at the downtown Honolulu monitoring station. The annual second-highest 1-hour concentrations ranged from 1.1 to 1.8 ppm. The annual second-highest 8-hour concentrations ranged from 0.8 to 1.0 ppm. No exceedances of the state or national 1-hour or 8-hour AAQS were reported.

Nitrogen dioxide is monitored by the Department of Health at the Kapolei monitoring station, which is about 16 miles west of the project area. Annual average concentrations of this pollutant ranged from 0.003 to 0.005 ppm, safely inside the state and national AAQS. A new 1-hour standard for nitrogen dioxide was implemented during 2010. Data pertaining to this new standard are not shown in Table 4. Based on the information available, exceedance of the new 1-hour standard for nitrogen dioxide within the study area is very unlikely.

The nearest available ozone measurements were obtained at Sand Island (just west of the project area). The annual fourth-highest 8-hour concentrations (which are most relevant to the standards) for the period 2007 through 2011 ranged between 0.033 and 0.048 ppm, which is well inside the state and federal standards. The 8-hour standard for ozone did not exist prior to 2002. Prior to 2002, the now obsolete state 1-hour standard was typically exceeded several times each year.

Although not shown in the table, the nearest and most recent measurements of ambient lead concentrations that have been reported were made at the downtown Honolulu monitoring station between 1996 and 1997. Average quarterly concentrations were near or below the detection limit, and no exceedances of the state AAQS were recorded. Monitoring for this parameter was discontinued during 1997.

Based on the data and discussion presented above, it appears likely that the State of Hawaii AAQS for sulfur dioxide, nitrogen dioxide, particulate matter, ozone and lead are currently being met in the project area. While carbon monoxide measurements at the downtown Honolulu monitoring station suggest that concentrations are within the state and national standards, local "hot spots" may exist near traffic-congested intersections. The potential for this within the project area is examined later in this report.

6.0 SHORT-TERM IMPACTS OF PROJECT

Implementation of the Kaka'ako TOD Overlay Plan would likely result in the construction of up to 14 million square feet of additional residential space compared to without the Plan. Short-term direct and indirect impacts on air quality could potentially occur due to this construction. For development of this nature, there are two potential types of air pollution emissions that could directly result in short-term air quality impacts during construction: (1) fugitive dust from vehicle movement, soil excavation and demolition activities; and (2) exhaust emissions from on-site construction equipment. Indirectly, there also could be short-term impacts from slow-moving construction equipment traveling to and from the project site, from a temporary increase in local traffic caused by commuting construction workers, and from the disruption of normal traffic flow caused by roadway lane closures.

Fugitive dust emissions may arise from the grading and dirt-moving activities associated with site clearing and preparation work. The emission rate for fugitive dust emissions from construction activities is difficult to estimate accurately. This is because of its elusive nature of emission and because the potential for its generation varies greatly depending upon the type of soil at the construction site, the amount and type of dirt-disturbing activity taking place, the moisture content of exposed soil in work areas, and the wind speed. The EPA [3] has provided a rough estimate for uncontrolled fugitive dust emissions from construction activity of 1.2 tons per acre per month under conditions of "medium" activity, moderate soil silt content (30%), and precipitation/evaporation (P/E) index of 50. Uncontrolled fugitive dust emissions at the project site could be somewhere

near that level, depending on the amount of rainfall that occurs. In any case, State of Hawaii Air Pollution Control Regulations [4] prohibit visible emissions of fugitive dust from construction activities at the property line. Thus, an effective dust control plan for the project construction is essential.

Adequate fugitive dust control can usually be accomplished by the establishment of a frequent watering program to keep bare-dirt surfaces in construction areas from becoming significant sources of dust. In dust-prone or dust-sensitive areas, other control measures such as limiting the area that can be disturbed at any given time, applying chemical soil stabilizers, mulching and/or using wind screens may be necessary. Control regulations further stipulate that open-bodied trucks be covered at all times when in motion if they are transporting materials that could be blown away. Haul trucks tracking dirt onto paved streets from unpaved areas is often a significant source of dust in construction areas. Some means to alleviate this problem, such as road cleaning or tire washing, may be appropriate. Paving of parking areas and/or establishment of landscaping as early in the construction schedule as possible can also lower the potential for fugitive dust emissions.

On-site mobile and stationary construction equipment also will emit air pollutants from engine exhausts. The largest of this equipment is usually diesel-powered. Nitrogen oxides emissions from diesel engines can be relatively high compared to gasoline-powered equipment, but the annual standard for nitrogen dioxide is not likely to be violated by short-term construction equipment emissions. Also, the new short-term (1-hour) standard for nitrogen dioxide is based on a three-year average; thus it is

unlikely that relatively short-term construction emissions would exceed the standard. Carbon monoxide emissions from diesel engines are low and should be relatively insignificant compared to vehicular emissions on nearby roadways.

Project construction activities could obstruct the normal flow of traffic for short periods of times such that overall vehicular emissions in the project area could temporarily increase. The only means to alleviate this problem will be to attempt to keep roadways open during peak traffic hours and to move heavy construction equipment and workers to and from construction areas during periods of low traffic volume. Thus, most potential short-term air quality impacts from project construction can be mitigated.

7.0 LONG-TERM IMPACTS OF PROJECT

Implementation of the Kaka'ako TOD Overlay Plan is expected to result in up to 14 million square feet of additional residential development. This additional residential development could result in added traffic volumes and/or changes in traffic patterns in the project area. This could potentially cause long-term impacts on ambient air quality in the project area. Motor vehicles with gasoline-powered engines are significant sources of carbon monoxide. They also emit nitrogen oxides and other contaminates.

Federal air pollution control regulations require that new motor vehicles be equipped with emission control devices that reduce emissions significantly compared to a few years ago. In 1990, the President signed into law the Clean Air Act Amendments. This

legislation required further emission reductions, which have been phased in since 1994. More recently, additional restrictions were signed into law during the Clinton administration, and these began to take effect during the next decade. The added restrictions on emissions from new motor vehicles will lower average emissions each year as more and more older vehicles leave the state's roadways. It is estimated that carbon monoxide emissions, for example, will go down by an average of about 25 percent per vehicle during the next 20 years due to the replacement of older vehicles with newer models.

To evaluate the potential long-term ambient air quality impact of motor vehicle traffic, computerized emission and atmospheric dispersion models can be used to estimate ambient carbon monoxide concentrations along roadways within the project area. Carbon monoxide is selected for modeling because it is both the most stable and the most abundant of the pollutants generated by motor vehicles. Furthermore, carbon monoxide air pollution is generally considered to be a microscale problem that can be addressed locally to some extent, whereas nitrogen oxides air pollution most often is a regional issue that cannot be addressed by a single project.

For this project, three scenarios were selected for the carbon monoxide modeling study: (1) year 2013 with present conditions, (2) year 2035 without the project, and (3) year 2035 with the project. To begin the modeling study of the three scenarios, critical receptor areas in the vicinity of the project were identified for analysis. Generally speaking, roadway intersections are the primary concern because of traffic congestion and because of the increase in vehicular emissions

associated with traffic queuing. For this study, ten of the key intersections identified in the project traffic study [5] were also selected for air quality analysis. These included the following intersections:

- Kapiolani Boulevard at South Street
- Kapiolani Boulevard at Ward Avenue
- Kapiolani Boulevard at Pensacola Street
- Kapiolani Boulevard at Piikoi Street
- Ala Moana Boulevard at South Street
- Ala Moana Boulevard at Cooke Street
- Ala Moana Boulevard at Ward Avenue
- Ala Moana Boulevard at Piikoi Street
- Queen Street at Ward Avenue
- Bishop Street at King Street.

The above intersections are locations with generally higher traffic volumes and/or lower level-of-service conditions that were included in the project traffic study and are likely locations within or nearby the project area where carbon monoxide concentrations are or will be higher. The traffic impact report for the project describes the existing and projected future traffic conditions and laneage configurations of the study intersections in detail. In performing the air quality impact analysis, it was assumed that all recommended traffic mitigation measures would be implemented.

The main objective of the modeling study was to estimate maximum 1-hour average carbon monoxide concentrations for each of the three scenarios studied. To evaluate the significance of the

estimated concentrations, a comparison of the predicted values for each scenario can be made. Comparison of the estimated values to the national and state AAQS was also used to provide another measure of significance.

Maximum carbon monoxide concentrations typically coincide with peak traffic periods. The traffic impact assessment report evaluated morning and afternoon peak traffic periods. These same periods were evaluated in the air quality impact assessment.

Vehicular carbon monoxide emissions for each year studied were calculated using EPA’s Motor Vehicle Emission Simulator (MOVES) computer model [6]. One of the key inputs to MOVES is vehicle mix. Unless very detailed information is available, national average values are typically assumed, which is what was used for the present study. Ambient temperatures of 59 and 68 degrees F were used for morning and afternoon peak-hour emission computations, respectively, although MOVES emission estimates are not highly sensitive to ambient temperature within the relatively small range that occurs in Hawaii.

After computing vehicular carbon monoxide emissions through the use of MOVES, these data were then input to an atmospheric dispersion model. EPA air quality modeling guidelines [7] currently recommend that the computer model CAL3QHC [8] be used to assess carbon monoxide concentrations at roadway intersections, or in areas where its use has previously been established, CALINE4 [9] may be used. Until a few years ago, CALINE4 was used extensively in Hawaii to assess air quality impacts at roadway intersections. In December 1997, the

California Department of Transportation recommended that the intersection mode of CALINE4 no longer be used because it was thought the model had become outdated. Studies have shown that CALINE4 may tend to over-predict maximum concentrations in some situations. Therefore, CAL3QHC was used for the subject analysis.

CAL3QHC was developed for the U.S. EPA to simulate vehicular movement, vehicle queuing and atmospheric dispersion of vehicular emissions near roadway intersections. It is designed to predict 1-hour average pollutant concentrations near roadway intersections based on input traffic and emission data, roadway/receptor geometry and meteorological conditions.

Input peak-hour traffic data were obtained from the traffic study cited previously. This included vehicle approach volumes, saturation capacity estimates, intersection laneage and signal timings. All emission factors that were input to CAL3QHC for free-flow traffic on roadways were obtained from MOVES based on assumed free-flow vehicle speeds corresponding to the posted or design speed limits.

Model roadways were set up to reflect roadway geometry, physical dimensions and operating characteristics. Concentrations predicted by air quality models generally are not considered valid within the roadway-mixing zone. The roadway-mixing zone is usually taken to include 3 meters on either side of the traveled portion of the roadway and the turbulent area within 10 meters of a cross street. Model receptor sites were thus located at the edges of the mixing zones near all intersections that were studied

for all three scenarios. This acknowledges that pedestrian sidewalks already exist in these locations. All receptor heights were placed at 1.8 meters above ground to simulate levels within the normal human breathing zone.

Input meteorological conditions for this study were defined to provide "worst-case" results. One of the key meteorological inputs is atmospheric stability category. For these analyses, atmospheric stability category 5 was assumed for the morning cases, while atmospheric stability category 4 was assumed for the afternoon cases. These are the most conservative stability categories that are generally used for estimating worst-case pollutant dispersion within urban areas for these periods. A surface roughness length of 100 cm and a mixing height of 1000 meters were used in all cases. Worst-case wind conditions were defined as a wind speed of 1 meter per second with a wind direction resulting in the highest predicted concentration. Concentration estimates were calculated at wind directions of every 5 degrees.

Existing background concentrations of carbon monoxide in the project vicinity are believed to be at relatively low levels. Thus, background contributions of carbon monoxide from sources or roadways not directly considered in the analysis were accounted for by adding a background concentration of 1.0 ppm to all predicted concentrations for 2013. Although increased traffic is expected to occur within the project area within the next several years with or without the project, background carbon monoxide concentrations may not change significantly since individual emissions from motor vehicles are forecast to decrease with time.

Hence, a background value of 1.0 ppm was assumed to persist for the future scenarios studied.

Predicted Worst-Case 1-Hour Concentrations

Table 5 summarizes the final results of the modeling study in the form of the estimated worst-case 1-hour morning and afternoon ambient carbon monoxide concentrations. These results can be compared directly to the state and the national AAQS. Estimated worst-case carbon monoxide concentrations are presented in the table for three scenarios: year 2013 with existing traffic, year 2035 without the project and year 2035 with the project. The locations of these estimated worst-case 1-hour concentrations all occurred at or very near the indicated intersections.

As indicated in the table, the highest estimated 1-hour concentration within the project vicinity for the present (2013) case was 2.6 ppm. This was projected to occur during the morning peak traffic hour near the intersection of Ala Moana Boulevard at Ward Avenue. Concentrations at other locations and times studied were 2.5 ppm or lower. Predicted worst-case 1-hour concentrations at all locations studied for the 2013 scenario were well within both the national AAQS of 35 ppm and the state standard of 9 ppm.

In the year 2035 without the proposed project, the highest worst-case 1-hour concentration was predicted to occur during the morning at two locations. These were the intersections of Ala Moana Boulevard at Cooke Street and Kapiolani Boulevard at Ward Avenue. A value of 2.1 ppm was predicted to occur at these locations and time. Peak-hour worst-case values at the other

locations and times studied for the 2035 without project scenario ranged between 1.6 and 2.0 ppm. Compared to the existing case, predicted concentrations for the year 2035 without the project decreased by about 10 to 20 percent at most locations and worst-case concentrations remained well within the state and national standards.

Predicted 1-hour worst-case concentrations for the 2035 with project scenario did not change significantly at the study intersections compared to without the project in 2035. The maximum concentration was predicted to occur during the morning at the intersection of Ala Moana Boulevard at Ward Avenue, increasing slightly compared to the without project scenario to a concentration of 2.2 ppm. Other concentrations ranged between 1.6 and 2.1 ppm. Worst-case concentrations at all locations studied remained well within the state and federal standards.

Predicted Worst-Case 8-Hour Concentrations

Worst-case 8-hour carbon monoxide concentrations were estimated by multiplying the worst-case 1-hour values by a persistence factor of 0.6. This accounts for two factors: (1) traffic volumes averaged over eight hours are lower than peak 1-hour values, and (2) meteorological conditions are more variable (and hence more favorable for dispersion) over an 8-hour period than they are for a single hour. Based on monitoring data, 1-hour to 8-hour persistence factors for most locations generally vary from 0.4 to 0.8 with 0.6 being the most typical. One study based on modeling [10] concluded that 1-hour to 8-hour persistence factors could typically be expected to range from 0.4 to 0.5. EPA guidelines [11] recommend using a value of 0.7 unless a locally derived

persistence factor is available. Recent monitoring data for locations on Oahu reported by the Department of Health [12] suggest that this factor may range between about 0.2 and 0.6 depending on location and traffic variability. Considering the location of the project and the traffic pattern for the area, a 1-hour to 8-hour persistence factor of 0.6 will likely yield reasonable estimates of worst-case 8-hour concentrations.

The resulting estimated worst-case 8-hour concentrations are indicated in Table 6. For the 2013 scenario, the estimated worst-case 8-hour carbon monoxide concentrations for the ten locations studied ranged from 1.1 to 1.6 ppm, with the highest concentration occurring at the intersection of Ala Moana Boulevard and Ward Avenue. The estimated worst-case concentrations for the existing case were well within both the state standard of 4.4 ppm and the national limit of 9 ppm.

For the year 2035 without project scenario, worst-case concentrations ranged between 1.0 and 1.3 ppm, with the highest concentration occurring at the intersections of Ala Moana Boulevard at Cooke Street and Kapiolani Boulevard at Ward Avenue. All predicted concentrations were within the standards.

For the 2035 with project scenario, worst-case concentrations remained nearly unchanged compared to the without project case, indicating minimal project impact. All predicted 8-hour concentrations for this scenario were well within both the national and the state AAQS.

Conservativeness of Estimates

The results of this study reflect several assumptions that were made concerning both traffic movement and worst-case meteorological conditions. One such assumption concerning worst-case meteorological conditions is that a wind speed of 1 meter per second with a steady direction for 1 hour will occur. A steady wind of 1 meter per second blowing from a single direction for an hour is extremely unlikely and may occur only once a year or less. With wind speeds of 2 meters per second, for example, computed carbon monoxide concentrations would be only about half the values given above. The 8-hour estimates are also conservative in that it is unlikely that anyone would occupy the assumed receptor sites (within 3 m of the roadways) for a period of 8 hours.

8.0 CONCLUSIONS AND RECOMMENDATIONS

The major potential short-term air quality impact of implementing the proposed Kaka’ako TOD Overlay Plan could occur from the emission of fugitive dust during the construction of additional residential units. Uncontrolled fugitive dust emissions from construction activities could amount to about 1.2 tons per acre per month, depending on rainfall. To control dust, active work areas and any temporary unpaved work roads should be watered at least twice daily on days without rainfall. Use of wind screens and/or limiting the area that is disturbed at any given time will also help to contain fugitive dust emissions. Wind erosion of inactive areas of the site that have been disturbed could be controlled by mulching or by the use of chemical soil stabilizers. Dirt-hauling trucks should be covered when traveling on roadways to prevent windage. A routine road cleaning and/or tire washing program will also help to reduce fugitive dust emissions that may

occur as a result of trucks tracking dirt onto paved roadways in the project area. Establishment of landscaping early in the construction schedule will also help to control dust.

During construction phases, emissions from engine exhausts (primarily consisting of carbon monoxide and nitrogen oxides) will also occur both from on-site construction equipment and from vehicles used by construction workers and from trucks traveling to and from the project. Increased vehicular emissions due to disruption of traffic by construction equipment and/or commuting construction workers can be alleviated by moving equipment and personnel to the site during off-peak traffic hours.

Implementing the proposed Kaka'ako TOD Overlay Plan could result in changes in motor vehicle traffic patterns or volumes within the study area. Analysis of existing and projected future motor vehicle traffic with and without the proposed Plan indicates that any long-term impacts on air quality in the project area due to emissions from project-related motor vehicle traffic should be insignificant. Worst-case concentrations of carbon monoxide should remain within both the state and the national ambient air quality standards through the year 2035 with or without the proposed Plan. Implementing any air quality mitigation measures for long-term traffic-related impacts is unnecessary and unwarranted.

ECONOMIC IMPACT ASSESSMENT OF PROPOSED KAKA'AKO RULE CHANGES FOR TRANSIT-ORIENTED DEVELOPMENT

October 15, 2014

Prepared for:
Lee Sichter LLC
and
Hawai'i Community Development Authority

Prepared by:
John M. Knox & Associates, Inc.

SUMMARY

This economic impact report was prepared by John M. Knox & Associates, Inc. ("JMK Associates") in conjunction with an overall Environmental Impact Statement (EIS) – and is intended to be appended to and summarized within that EIS – on the consequences of revising the Hawai'i Community Development Authority (HCDA) Plans for future development in the Kaka'ako Community Development District (hereafter referred to simply as "Kaka'ako").

The HCDA is contemplating adoption of a new "TOD Overlay Plan" that would augment existing development Rules governing the various parts of Kaka'ako. The TOD Overlay Plan would, among other things, involve (a) increased heights and densities around planned Honolulu Authority for Rapid Transit (HART) rail stations; and (b) potential development of three hotels.

The primary analysis for the Proposed Alternatives considers:

- Population and economic effects that could flow from complete build-out of Kaka'ako under the current Rules, a situation termed the *"**Future Baseline Condition**."*
- Similar effects that could flow from complete build-out under the TOD Overlay Plan, a scenario termed *"**TOD Alternative A**"*, as well as for a slightly more conservative *"**TOD Alternative B**"* (with lower height limits). For planning purposes, all of the proposed scenarios are assumed to build out by 2035, though in reality it could be longer.

The difference between these future alternatives constitutes the "impact" of these Proposed Actions for any particular topic – e.g., for population or for jobs.

Key Concepts and Caveats: The alternatives referenced above represent HCDA *visions* of how it would like to see Kaka'ako develop in the future. These visions may or may not ever be realized, because the vast majority of Kaka'ako is controlled by landowners who will make independent decisions about if and how they will redevelop their lands. Kaka'ako could develop in various ways under either scenario. For purposes of this analysis, the illustrative Future Baseline Condition is primarily based on a projection developed by HCDA when the current Rules were developed and analyzed. The TOD Alternatives A and B are based on assumptions about changed development patterns created by other consultants during this EIS process.

Analysis is done at two levels: (1) *Kaka'ako-specific* population and employment impacts consider only differences within the Kaka'ako boundaries, though much of this comes from simply shifting population or economic activities from other parts of O'ahu into Kaka'ako. (This is another key concept – for the most part, the Proposed Alternatives would simply allow Kaka'ako to "capture" different amounts of residential or commercial activity that would happen anyway somewhere on O'ahu.) (2) *Islandwide*

impacts are actually smaller, because they are limited to proposed components that presumably would not happen at all under the Future Baseline Condition – by convention, these would primarily be (a) the three hotels, plus (b) some increase in part-time residents (i.e., off-island sources of new spending), as well as (c) any public infrastructure/facility development attributable to net islandwide population or housing impacts of the TOD Alternatives.

Kaka'ako-Specific Impacts of the TOD Alternatives: The following table shows Kaka'ako-wide estimates flowing from the illustrative scenarios used for the analysis. The full report contains additional breakdowns by area and population/job subcategories.

Summary of Key Kaka'ako-Specific Results

	Residential Units	Full-Time Residential Population	Average De Facto Population[1]	Total Operational Jobs at Build-Out[2]	*Office Jobs Only*	Cumulative Construction Jobs from Full Build-Out[3]
Future Baseline Condition	21,146	33,466	33,844	51,207	*37,186*	55,838
TOD Alternative B	26,588	42,477	44,465	43,651	*29,474*	69,220
Impact (Difference)	*5,443*	*9,011*	*10,621*	*-7,555*	*-7,712*	*13,382*
TOD Alternative A	28,968	46,181	48,223	45,157	*30,397*	76,196
Impact (Difference)	*7,822*	*12,715*	*14,379*	*-6,050*	*-6,789*	*20,359*

[1] "De Facto" Pop. = Full-Time Residents Minus Those Temporarily Away, Plus Part-Time Residents and (for TOD Alternatives A and B) Hotel Guests

[2] Total Full- and Part-Time Jobs, All Shifts and Days of Week

[3] In Job-Years (both full- and part-time); includes some "soft-cost" (architect-engineer) jobs; includes construction of additional public infrastructure and government facilities attributable for each scenario

Assuming full build-out, each of the TOD Alternatives generates more population, fewer operational jobs, but more cumulative construction employment in Kaka'ako than does the Future Baseline Condition. Office jobs are broken out above to show they would constitute the majority of operational jobs under either scenario. It is particularly uncertain whether the O'ahu economy would generate demand for so many Office jobs by the assumed 2035 planning horizon.

While all public services and facilities will be impacted by population growth throughout urban Honolulu, responses from affected agencies suggest that impacts of both TOD Alternatives A and B on Kaka'ako-area schools and recreational facilities could be significant. (Park/recreational impacts are considered an "Unresolved Issue" until HCDA completes a study of needs and master plan for the area.) An additional fire station is likely also needed under both Alternative A and Alternative B.

Statewide/Islandwide Impacts of the TOD Alternatives: Most results calculated for this study are technically statewide, but the overwhelming majority would be on O'ahu. For both TOD Alternatives, islandwide impacts flow from an assumed three new hotels, as well as from an estimated increase in average daily population of part-time residents (694 for Alternative A, 356 for Alternative B), as well as construction of additional public infrastructure/facilities required. For simplicity, only "impact" numbers are shown below for each of the Alternatives.

Summary of Key Islandwide Impacts Under TOD Alternative B

Cumulative Construction Effects	Impacts	Average Annual Operational Effects	Impacts
Total Economic Activity ($ Millions)[1]	$496	Total Economic Activity ($ Millions)[1]	$324
Total Household Earnings ($ Millions)	$150	Total Household Earnings ($ Millions)	$94
Total Jobs (Worker-Years) Supported[2]	2,660	Total Jobs (Full-/Part-Time) Supported[2]	2,497
Associated Resident Pop. Supported[2]	4,934	Associated Resident Pop. Supported[2]	4,934
		Avg. Daily Visitor Population Increase[3]	2,106

[1] "Totals" in this table include direct + indirect/induced "ripple effects" statewide (with vast majority on O'ahu)

[2] "Supported" jobs and associated resident population could be either new or existing but maintained by project

[3] Sum of 1,752 hotel guests and 354 increase in part-time residents -- this number is also Kaka'ako-specific

Summary of Key Islandwide Impacts Under TOD Alternative A

Cumulative Construction Effects	Impacts	Average Annual Operational Effects	Impacts
Total Economic Activity ($ Millions)[1]	$474	Total Economic Activity ($ Millions)[1]	$351
Total Household Earnings ($ Millions)	$144	Total Household Earnings ($ Millions)	$101
Total Jobs (Worker-Years) Supported[2]	2,680	Total Jobs (Full-/Part-Time) Supported[2]	2,709
Associated Resident Pop. Supported[2]	5,009	Associated Resident Pop. Supported[2]	5,354
		Avg. Daily Visitor Population Increase[3]	2,364

[1] "Totals" in this table include direct + indirect/induced "ripple effects" statewide (with vast majority on O'ahu)

[2] "Supported" jobs and associated resident population could be either new or existing but maintained by project

[3] Sum of 1,671 hotel guests and 693 increase in part-time residents -- this number is also Kaka'ako-specific

Analysis of government costs and revenues is complicated by various uncertainties (such as whether public funds will be needed for parks, or whether new impact fees or other mechanisms to capture revenue from developers/consumers will be developed). However, the illustrative analysis for this report suggests the State will see a significant annual positive balance from operational elements of each TOD Alternative, A and B. Given some conservative assumptions, the State's balance from construction alone could be negative, but the positive operational balance and build-out would be enough to offset this loss in a single year.

The City and County situation is more neutral – figures mostly hovering a little above zero for both construction and operations, though a little negative for operations under TOD Alternative A only. That apparent negative balance is very small, and would be turned to a small positive balance if the State decides to restore more Transient Accommodations Tax funds to counties in the future.

CONTENTS

1. INTRODUCTION 1-1

1.1 Purpose and General Project Description 1-1

1.2 Unique Study Aspects and Caveats 1-2

1.3 Study Area 1-3

1.4 Impact Assessment Logic and Scenarios 1-4

1. INTRODUCTION

This introductory chapter is intended to:

1. Explain the purpose of the overall report;
2. Note some unique study aspects and caveats;
3. Describe the study area for the project; and
4. Explain the alternatives and logic of impact assessment in this report.

1.1 Purpose and General Project Description

This economic impact report was prepared in conjunction with an overall Environmental Impact Statement (EIS) – and is intended to be appended to and summarized within that EIS – on the consequences of revising the Hawai'i Community Development Authority (HCDA) Plans for future development in the Kaka'ako Community Development District (hereafter referred to simply as "Kaka'ako"). The current Plans (each with associated administrative Rules)[1] governing Kaka'ako are in several parts:

1. The October 2005 *Makai Area Plan* governs the part of Kaka'ako between Ala Moana Blvd. and the ocean – it has been supplemented by an April 2011 *Kaka'ako Makai Conceptual Master Plan*.

2. The September 2011 *Mauka Area Plan* governs the part above Ala Moana Blvd., the greater portion of Kaka'ako, and the only one with current or planned residential population living in developed structures.

The current EIS addresses consequences of modifying these plans by official adoption of either (1) the Draft Transit Oriented Development Plan and Rules Overlay ("TOD Overlay Plan"),[2] which became the basis for the "TOD Alternative A" discussed in the following Section 1.4, or else (2) a lower-density version of the same Plan, which became the basis for the "TOD Alternative B" described in the same section. Another possible outcome is (3) HCDA rejection of both Alternatives in favor of retaining the current Rules, i.e., the "Future Baseline Condition" discussed in Section 1.4.

The TOD Overlay Plan contains many elements intended to improve the quality of life in Kaka'ako – particularly those related to "Complete Streets" design elements promoting more pedestrian and bicycling use, which in turn would help ensure a more vibrant mixed-used retail and commercial area. However, for purposes of this analysis, the most critical elements would involve ***(a) increased heights and densities around planned Honolulu Authority for Rapid Transit (HART) rail stations; and (b) potential development of three hotels***. These elements apply to both TOD Alternative A and also to Alternative B, albeit with somewhat lower heights and densities in certain

[1] All the indicated Plans and associated Rules are available on the HCDA website at: http://dbedt.hawaii.gov/hcda/plans-rules/

[2] Lee Sichter LLC, Nelson\Nygaard, VIA Architecture. May 20, 2013. "Kaka'ako Community Development District TOD Overlay Plan." (Draft). http://dbedt.hawaii.gov/hcda/transit-oriented-development/

Kaka'ako locations for Alternative B. Both Alternatives could result in more population, employment, and associated impacts than development under current Rules. Therefore, this analysis will sometimes use the phrase "TOD Alternatives" to refer to Alternative A and Alternative B jointly, in contrast to the Future Baseline Condition.

Either of the two TOD Alternatives could theoretically also result in the need for additional public infrastructure and/or facilities and services – and to the extent these can be identified, their economic effects also figure into the analysis.

1.2 Unique Study Aspects and Caveats

The great majority of this report is concerned not with specific proposals that developers want to see happen, but with government agency (HCDA) plans (the TOD Alternatives) that represent slightly different agency *visions* of how it would like to see Kaka'ako develop in the future. Such visions may or may not ever be realized, because the vast majority of Kaka'ako is controlled by landowners who will make independent decisions about if and how they will redevelop their lands, within the parameters of the proposed Rules.

Either version of the proposed new Rules could permit certain new activities, such as limited hotel development, but they do not guarantee that any such development ever will actually take place. That will depend on economic feasibility and market realities.

An important example of this caveat involves ***office space development***. Current Rules permit substantial office development, and the HCDA's vision for what that might mean was captured in a dataset generated by HCDA in 2009, laying out a building-by-building vision for a future Kaka'ako developed under the current Rules (see Chapter 2, Section 2.1.1). This included a large amount of office space. The TOD Alternatives would likely generate *less* office space, but still a potentially large amount.

In reality, little in the way of new office development has occurred in Kaka'ako in recent years, and existing office space in Downtown Honolulu has large vacancy rates. Thus, it is very possible that only a small fraction of the potential new Kaka'ako office space envisioned under either current or potential new Rules will actually be developed by the 2035 build-out timeframe assumed for EIS purposes, though it could occur thereafter. This is worth noting, because the potential number of jobs projected for Kaka'ako is quite large – but most of those jobs are associated with office development. However, again, this study analyzes not specific proposed office space by people actually planning to build it, but rather an HCDA vision in which Kaka'ako is developed in this way.

Another unique aspect of this study flows from the HCDA building-by-building datasets (including an "Existing" dataset). This resulted in an ***unusually complex methodology*** – described at length in Chapter 2 – that necessarily involves detailed description of the ways these datasets were used, not just (as is more typical) assumed values of standard multipliers such as household sizes or job ratios for various economic activities.

1.3 Study Area

Kaka'ako includes about 605 acres and consists of three distinct areas – from smallest to largest:

1. The **Aloha Tower Special District** (about 3.4 acres) is a non-contiguous parcel adjacent to HART's proposed downtown station and to the Aloha Tower Marketplace (which is not a part of the HCDA Aloha Tower Special District). Bounded by Richards St., Bishop St., and Aloha Tower Dr., it is the current site of a Hawaiian Electric Co. (HECO) power facility that may eventually be redeveloped.

2. The **Makai Area** (approximately 151.6 acres) is on the ocean (makai) side of Ala Moana Blvd., and is bounded by Ala Moana Regional Park and the property line between Pier 2 and Pier 4 at the Honolulu Harbor shoreline.

3. The **Mauka Area** (about 450 acres) is the area on the mountain (mauka) side of Ala Moana Blvd., and also bounded by Pi'ikoi St., Punchbowl St., and King St. It consists of seven "Neighborhood Zones" – ***Pauahi*** (where much of the property is owned by the Kamehameha Schools), ***Auahi*** (location of most of the lands owned by Kaka'ako's other large landowner, the Howard Hughes Corporation), ***Kapi'olani***, ***Central Kaka'ako***, ***Civic Center***, ***Sheridan***, and the ***Thomas Square District*** (which is actually makai of, and does not contain, the Thomas Square Park).

1.4 Impact Assessment Logic and Scenarios

Logic: For physical environmental impacts, it usually makes sense to assume that future conditions without adoption of either TOD Alternative A or Alternative B would simply involve a continuation of current conditions. But for economic assessment, the future without the new Plan is not what is there now – rather, it would be development under currently approved Rules.

Therefore, an economic "impact" is not change from present conditions, but rather the ***difference between two estimated futures*** – i.e., the difference in population, jobs, etc. between what is estimated to be possible under either one of the TOD Alternatives, versus what is estimated to occur under existing Plans and Rules ("Future Baseline Condition"). The word "Scenario" will be used as a generic term covering future "Alternatives" and "Conditions," as well as an "Existing Scenario" (below).

Scenarios: The logic thus involves four Scenarios, though only three of them are directly used to calculate two different sets of numerical "impacts" –

1. The **Existing Scenario** represents the best estimate of current conditions. It is not directly used for impact calculations, but is important for context and for some topics is necessary to calculate the numbers used for all future scenarios (for example, new building construction cannot be estimated without knowing what is there now).

2. The **Future Baseline Condition** is the term that will be used to describe what is estimated to happen under current Plans and Rules – i.e., without adoption and implementation of the TOD Alternatives described below.

3. **"TOD Alternative A" and "TOD Alternative B"** are terms that will be used to describe what is estimated to happen under some variant of the TOD Overlay Plan.

   - **Alternative A** is what is exactly described in the Draft TOD Overlay Plan referenced earlier. It includes the possibility of several 700-foot towers. The economic impact assessment for TOD Alternative A was mostly completed in 2013[3] (except for infrastructure costs needed from other consultant team members, without which the fiscal cost-revenue analysis could not be finished).

   - **Alternative B** is the TOD Overlay Plan variant with lower heights and densities in certain areas. This was developed by other members of the consultant team in response to action by the 2014 Hawaii State Legislature setting forth lower height limits for Kaka'ako in response to concerns about visual impacts. The specifications for Alternative B were developed in August 2014, and those results – along with some small adjustments to Alternative A – were analyzed in August and September of 2014.

[3] Because most of this report was done in 2013, dollar figures are primarily in 2012 dollars, as this was the basis for many figures available at that time. Results for Alternative B were kept in 2012 dollars.

Figure 1.2 shows how these scenarios relate to the concept of economic "impact."

Figure 1.2: Conceptual Graph – Scenarios and "Impact"

Implication of the Term "Scenario" for This Analysis: Many EIS's use the term "scenario," because exact future realities can never be definitively known in advance, and so it is necessary to develop a reasonable set of assumptions about quantitative aspects in order to do calculations. For virtually any EIS, economic "scenarios" mean an imagined but reasonable single version of the many possible outcomes that could describe the points in time being compared. It is therefore a standard rule of economic assessment to create scenarios/alternatives that are "conservative" in the sense of being more likely to err on the side of a larger impact than a smaller impact.

For this analysis, though, the term "scenario" is particularly apt, as it implies a possible but not certain outcome. As previously noted, the Kaka'ako situation differs greatly from situations in many EIS's. Yet another difference is that many EIS's are triggered by proposed actions that have specific characteristics at the time of the proposal but may turn out to be somewhat different. For example, a resort development that seeks overall land use approvals may be initially described as having 500 hotel units and 500 timeshare units, but due to market conditions or other factors is actually later built to have 400 hotel units and 600 timeshares – i.e., the range of realistic outcomes can vary somewhat from the specific EIS scenario.

However, in the case of Kaka'ako, the range of possible future realities is particularly great. The HCDA is a development authority, not a landowner. How landowners will actually respond to opportunities under either the current or proposed Plans/Rules will depend on many factors that simply cannot be known for sure – economic cycles, availability of capital, idiosyncratic personal or geographical factors affecting possible land consolidation, etc.

It would be impossible to conduct a quantitative analysis without making the sorts of assumptions that produce a "scenario." These assumptions are greatly facilitated by HCDA datasets, described further in Chapter 2, that model Kaka'ako structures on a building-by-building, block-by-block basis.

1.5 Other Issues Related to Logic of "Scenarios"

Timeframes Applied to Scenarios:

- The "Existing" scenario will be operationalized as meaning the year 2010. The building-specific, block-specific Kaka'ako datasets described in Chapter 2 were completed in 2009, shortly before the 2010 Census, and little actual new developments were finished in the interim (or, for that matter, the time between 2010 and 2013, though a substantial number of new projects are now underway or are in the planning stages).

- Both the "Future Baseline Condition" and both the "TOD Alternatives" are nominally operationalized as potential situations in the year 2035, though in reality they depict a probable build-out situation (not necessarily maximal *total* development under the respective Plans/Rules, but the maximal *likely* development according to the various HCDA consultants who primarily developed them).

  An important unanswered, and currently unanswerable, question is the actual timing of this build-out. The analysis is conservative, in the sense of assuming maximal likely impacts, by concentrating the full range of potential development into the 2010-2035 time period. The analysis truly considers ***build-out of HCDA visions of Kaka'ako*** whenever they really occur.

Geographical Levels of Analysis within Kaka'ako: Although the methodology for the analysis in this report involves use of building-specific and block-specific assumptions from the previously mentioned datasets, ***results will be presented only on a Kaka'ako-wide basis***, ***and by large areas such as Mauka/Makai and the various Mauka "Neighborhood Zones."***

Both the current Mauka and Makai Plans, as well as the TOD Alternatives, provide landowners with the *opportunity* to redevelop in certain ways, but in no way *obligate* them to do so. Presenting block-specific results could be interpreted as attempting to influence landowner decisions, which would be inappropriate.

It was possible and appropriate to attempt to make reasonable assumptions and forecasts for small areas such as individual city blocks, then add up the individual results to obtain a Kaka'ako-wide outcome. However, many of those small-area results will inevitably be inaccurate. It is a principle of model-building that individual errors tend to cancel out, while still contributing to greater accuracy at the macro-level. An analogy would be life insurance companies predicting their total pay-outs by assessing the risks associated with each customer – the individual predictions may each be off to some degree, but the cumulative actuarial numbers are generally trustworthy.

Another geographical level of analysis is the islandwide one, reserved for certain parts of the study, as per the following discussion.

1.6 Other Issues Related to Logic of "Impacts" – Level of Impact

A final important issue has to do with whether "impacts" are determined as ***Kaka'ako-specific versus statewide/islandwide***.

1.6.1 Kaka'ako-Specific Impacts

A Kaka'ako-specific impact would be one that is confined to Kaka'ako itself (even if that impact is balanced by an accompanying reduction in some other part of the island).

For example, increased residential population growth within Kaka'ako due to higher densities under either of the TOD Alternatives generally means that people already on O'ahu would live in Kaka'ako rather than somewhere else, reducing numbers elsewhere on the island. ***Kaka'ako-specific impacts may in fact just be due to shifts in geographical location*** of economic and population activity that would be happening elsewhere anyway. That is, they may be "impacts" within the Kaka'ako boundaries or any identifiable areas from which they attract population, but from an islandwide perspective their net impacts may be essentially zero.

Kaka'ako-specific impacts are of particular interest to HCDA and Kaka'ako stake-holders, and so will be separately reported, labeled, and given detailed attention. Most of the report will focus on Kaka'ako-specific impacts.

1.6.2 Statewide / Islandwide Impacts

An islandwide impact would involve "net new" economic activity and/or population that either (a) occurs in Kaka'ako but is for some reason not balanced by a reduction elsewhere on the island (hence is a "net" gain); or (b) occurs outside of Kaka'ako as a result (via "ripple effects" from expenditures) of net new economic activity occurring within Kaka'ako.

An example of the latter would be if implementation of a TOD Alternative results in expanding O'ahu's economic base of "export" industries (primarily tourism and visitor expenditures) that bring new money into the state. Due to multiplier or "ripple effects" of outside money coming into the O'ahu economy, there could be additional spending, employment, and population throughout the entire state – however, the vast majority of these statewide effects would occur on O'ahu, so the distinction between "statewide" and "islandwide" effects is very, very small.

Relatively small proportions of planned future development under either the Future Baseline Condition or the TOD Alternatives would generate substantial "new" money, and so ***islandwide impacts will be fairly small*** compared to Kaka'ako-specific ones. Islandwide impacts are nevertheless presented because (a) this is the proper level for assessing impacts on State and County costs and revenues; and (b) it is important to understand that Kaka'ako-specific impacts for the most part are *not*

statewide/islandwide ones – e.g., additional full-time residential population in Kaka'ako does not mean an equal amount of growth in the islandwide population.

1.6.3 Project Components Generating Islandwide Impacts

Most of the Kaka'ako-specific impacts to be described would *not* be islandwide impacts. Just as with full-time residential population, most of the changes in economic activity (e.g., levels of retail, industrial, or office space) from the Future Scenario to either of the TOD Alternatives would simply be a matter of location – they are a function of the larger islandwide economy and market forces, and hence would be located somewhere on the island with or without this project.

However, the following elements *will* be assumed to be net new islandwide impacts –

- **Hotel Construction and Operations:** Both TOD Alternatives (A or B) envision up to three new hotels in Kaka'ako, and the scenarios for analysis assume development of three likely hotel types, as per guidance from HCDA – a business hotel, a condominium-hotel, and a traditional full-service hotel for travelers desiring to stay outside Waikīkī. Operational impacts of hotels flow from new visitor population and visitor spending throughout the state and island, not just in Kaka'ako.

  The actual development, nature, location, and characteristics of any Kaka'ako hotels will in reality be determined by market forces. It could be argued that if there is a market for three more urban Honolulu hotels, they would be developed somewhere on the island with or without this project. However, there is a very longstanding convention in Hawai'i EIS's for assuming that, without new entitlements, market forces would be thwarted and the requested new visitor units would not be developed elsewhere on island, at least without separate permits and entitlements subject to study in other EIS's.

- **Additional Levels of, and Spending by, Part-Residents:** Part-time residents are treated as "visitors" in most economic studies because, as with hotel guests, their spending represents new money in the economy and thereby generate new jobs. Census data noted later in this study indicate part-time residents already own units in Kaka'ako, and so their numbers would likely increase under either the Future Baseline Condition or the two TOD Alternatives (A or B). The object of this analysis is to estimate the likely *increment* in their numbers, spending, and associated economic impacts from the Future Baseline Condition to either of the TOD Alternatives.

  For purposes of this analysis, economic benefits associated with *construction* of new units ultimately occupied by this increment in part-time residents will conservatively *not* be counted among the islandwide impacts. No specific new buildings are (or, under existing or proposed Rules, could be) targeted for occupancy by part-time residents alone. If the part-time residential market were for some reason not to materialize after all, the additional residential capacity provided by either of the TOD

Alternatives would still be in place – but actual full build-out would just be somewhat delayed if the market consisted entirely of full-time Honolulu residents. (However, because part-time residents often spend significant sums to prepare new units for occupancy, impacts of such estimated initial one-time expenditures *will* be counted among the construction impacts.)

2. METHODS AND ASSUMPTIONS

The analysis was conducted in stages. Each stage had a distinct analytic approach and a distinct output:

1. **Kaka'ako-Specific Space for Various Building/Land Uses:** This stage involved application of information obtained primarily from or through other project consultants to develop (a) square footage for various specific building/land uses; and (b) the number of units of various types (e.g., full-time residential, part-time residential, and any visitor uses). The square footage output was used by other consultants (most immediately the traffic consultants) and also later for JMK Associates' own employment estimates. Results were computed for the Existing Scenario, the Future Baseline Condition, and both TOD Alternatives (A and B).

2. **Kaka'ako-Specific Population:** This stage also used some inputs from other consultants, along with U.S. Census data, to estimate both (a) full-time residential population, and also (b) "de facto" residential population (actual number of people staying there on an average day, including part-time residents and visitors). Results were generated for Existing, Future Baseline Condition, and both TOD Alternatives. (Note: *Islandwide* population impacts flowing from things like new hotels in Kaka'ako were separately studied as part of the "islandwide associated economic impacts" below.)

3. **Kaka'ako-Specific Operational Employment Impacts:**[4] This stage used land use square footage and/or units for each use, along with appropriate multipliers, to estimate total combined numbers of full- and part-time jobs in Kaka'ako for the Existing Scenario and –following future "build-out" of all proposed elements – for the Future Baseline Condition and for both TOD Alternatives.

4. **Kaka'ako-Specific Construction Employment Impacts:** This stage used assumed construction costs and information from the State of Hawaii Input-Output (I-O) Model to estimate cumulative construction full- and part-time jobs to achieve the visions for the Future Baseline Condition and both TOD Alternatives. Construction logically precedes operational employment, but includes public facility and infrastructure projects predicated in part on projected operational jobcounts. The analysis is discussed prior to "Public Facilities" (below) for the reader's ease, as it is conceptually parallel to the preceding analysis of operational employment impacts.

5. **Public Services and Facilities:** This analysis particularly focused on the Kaka'ako-specific level, though estimates are also made at the islandwide level.

[4] Kaka'ako-specific economic operational and construction impacts focused on employment only – as opposed to other possible economic effects, such as output and earnings – because operational jobs in particular were of primary concern for other consultant team members (traffic and infrastructure analysis).

6. **Statewide/Islandwide Construction-Related Economic Impacts:** This stage looked at construction from the *islandwide* perspective (technically *statewide*, but with the vast majority of impacts occurring on O'ahu – see detailed explanation in Section 2.6.2). It assumed that most construction of new Kaka'ako buildings would happen somewhere in the urban area or elsewhere on the island with or without either TOD Alternative (A or B) – key exceptions being new hotels and any Kaka'ako-specific public infrastructure or facility expenditures. The analysis utilized State I-O multipliers and hotel construction cost estimates.

7. **Estimated On-Site Operational Employment and Statewide/Islandwide Associated Economic Impacts:** By the same logic, this stage was effectively an analysis of the post-construction islandwide operational impacts associated just with the proposed new hotels (as well as spending by increased numbers of part-time residents). It used I-O multipliers and estimated visitor expenditures.

8. **Fiscal Cost-Revenue Impacts:** This stage used output from all the foregoing steps, as well as standard multipliers and some information from other HCDA consultants, to develop estimates of public costs and revenues. State and County governments are concerned with statewide and islandwide impacts, so the analysis is primarily at that level.

2.1 Estimated Space for Various Building/Land Uses

This initial stage (results in Chapter 3) was heavily focused on producing results needed by the project's traffic consultants, Nelson\Nygaard Consulting Associates, Inc. (herein-after "Nelson\ Nygaard"), though it also generated data for further stages of analysis by JMK Associates. As shortly noted, key inputs were spreadsheet datasets generated by HCDA, and so this stage was also completed using spreadsheet methodology.

2.1.1 Data Sources

Overview of Sources: The primary data sources were –

1. HCDA's original Synoptic Survey[5] output (for Mauka blocks, 2010 Existing and 2035 Future Baseline Condition) – further described below;

2. Projections for this study by VIA Architecture, Inc. ("VIA"), the urban design and TOD specialist retained by Lee Sichter LLC, for future land uses for:

   - Specific Kamehameha Schools (KS) and Howard Hughes (HH) blocks expected to be affected by TOD – for both the Future Baseline Condition (based on VIA analysis of KS and HH Master Plans) and both TOD Alternatives (A and B);

[5] In-house HCDA datasets generated in 2009, with final descriptions completed in 2010.

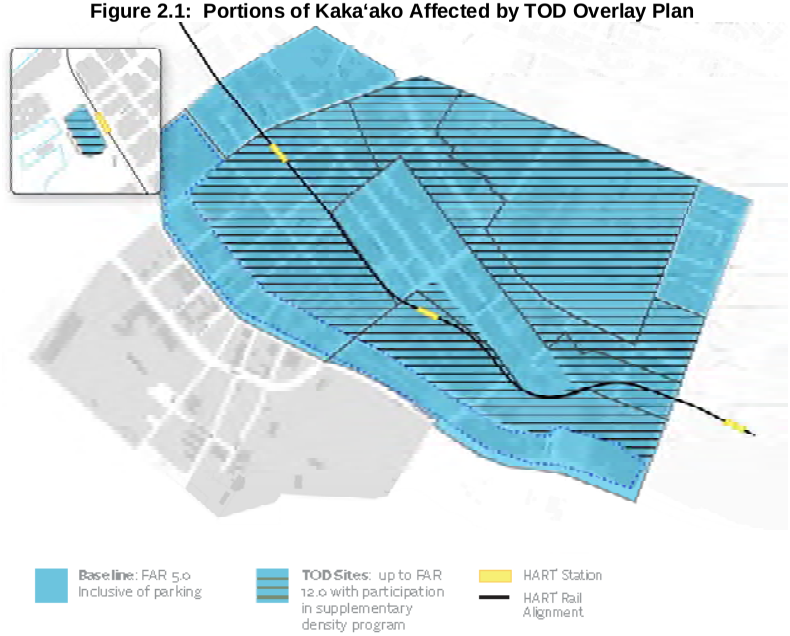
- Other Mauka blocks (non-KS and non-HH) expected to be affected by TOD – for the two TOD Alternatives only (as Future Baseline land uses for these blocks were incorporated in the HCDA numbers);

- Additional VIA modifications to certain HCDA Future Baseline block redevelopment assumptions to reflect (a) Industrial uses not included by HCDA;[6] and (b) needed reductions in other HCDA projected uses (e.g., Retail or Office) to accommodate the Industrial space;

- Makai lands and Aloha Tower Special District Site development – Future Baseline Condition and (for the Aloha Tower Special District Site only) both TOD Alternatives (A and B);

3. HCDA-selected 2013 updates to its original spreadsheet datasets (revised Future Baseline data for a few entitled projects, plus data on *existing* Makai activities);

4. Various further estimates and assumptions generated by JMK Associates.



HCDA Spreadsheets: A key foundation of the analysis – for both this stage and following ones – was the in-house set of spreadsheets made available by the HCDA for the "Existing" and "Future Baseline" scenarios. The original 2009 datasets provided a detailed estimate of numbers of units and land use square footages for all buildings (and in fact all *stories* [i.e., floors or levels] of all buildings) in the Mauka portion of Kaka'ako as of 2009, as well as forecasted future build-out under the 2009 Mauka Area rules.

For this analysis, the HCDA Existing and Future Baseline spreadsheet figures were updated for selected portions of Kaka'ako for which more recent information was available – e.g., the KS and HH Master Plans, which VIA used to provide JMK Associates with alternative Future Baseline numbers for certain blocks. Both the current KS and HH Master Plans were developed under the current Mauka Area Rules and therefore are properly considered part of the "Future Baseline." However, the original 2009 HCDA Future Baseline dataset used development assumptions for these blocks that were later modified in the KS and HH Master Plans.

As noted above, JMK Associates also used VIA projections to alter the original HCDA figures for some Future Baseline blocks and for all designated areas whose future development patterns were assumed to be affected by the new TOD-based Rules for either TOD Alternative (see Figure 2.1). For all other areas, the presumed pattern of development under either or both TOD Alternatives was assumed to be identical to the pattern under the Future Baseline Condition.

[6] HCDA's 2009 Synoptic Survey spreadsheets included Industrial uses in its Existing dataset but not in what we here term the Future Baseline one, apparently because the current Mauka Rules no longer break out Industrial as a separate category. However, for purposes of this analysis, it was appropriate to recognize and quantify Industrial uses in the Future Baseline dataset as well.

Figure 2.1: Portions of Kaka'ako Affected by TOD Overlay Plan

Source: Lee Sichter LLC, Nelson\Nygaard, VIA Architecture. May 20, 2013. "Kaka'ako Community Development District TOD Overlay Plan." (Draft). Figure 3-2, p. 3-4.

A critical implication of this approach is that very fine-grained and specific building-by-building assumptions were available for most parts of Kaka'ako, although (a) most of the Future Baseline building assumptions generated by HCDA were hypothetical; and (b) most VIA projections for the Future Baseline Condition and both TOD Alternatives involved more aggregated data – i.e., they were often cumulative block-level figures rather than building-by-building.

This means the numbers truly represent particular illustrative scenarios. These are valuable in terms of generating place-specific estimates – e.g., they can be used to produce arguably better results for the specific Kaka'ako districts or "Neighborhood Zones" used by HCDA for planning purposes. However, in generating quantitative models and estimates of this nature, errors are always likely to be greater at the more site-specific levels, and results are always likely to be more accurate at the larger levels. Therefore, as previously noted in Chapter 1, results are reported only at the levels of (a) Kaka'ako-wide; (b) broad area (Mauka, Makai, Aloha Tower Special District); and (c) Neighborhood Zone.

2.1.2 Land Use Categories

JMK Associates needed to use categories compatible with City definitions for estimating jobs from land uses in the third stage of this analysis. Despite different words used in land use labels by the City, HCDA spreadsheets, and VIA's initial input, the actual working categories were generally found to be consistent, or could be made so:

- Residential
- Hotel (for three properties in the TOD Alternatives only)
- Civic/Public (buildings designed for specific public uses, e.g., fire stations, hospitals)
- Office ("Commercial," usually interpreted as Office)
- Retail
- Industrial
- Surface Parking
- Garage Parking
- Medical/Educational (Nelson\Nygaard requested this category for the John A. Burns School of Medicine, or JABSOM, in the Makai area)
- Community Center (Nelson\Nygaard requested category for Children's Discovery Center).

Except for the last two categories and for "Hotel," HCDA used these categories or close equivalents for the Existing dataset. For the Future Baseline Condition, it used the same categories *except* for "Industrial," which ceased to become a separate land use category under the 2009 Mauka Area Rules. As described shortly (Section 2.1.4), JMK Associates estimated "Industrial" uses for the Future Baseline Condition (and these were carried over to both TOD Alternatives (A and B) where appropriate).

2.1.3 Geographical Areas and Block Numbering System

For purposes of this analysis, individual city blocks may be considered to fall into four main categories, for which land use figures came from predominantly different sources:

1. HCDA Mauka blocks (translated into a consistent numbering system[7] generated by VIA) – these will hereafter be called "VIA blocks" to indicate the blocks were initially identified by HCDA but final numbering came from VIA;

2. Makai block areas, including one for the Aloha Tower Special District Site, that were identified by VIA, corresponding to standard HCDA and City blocks – for purposes of simplification and because of their inclusion in a common numbering system, the general term "VIA blocks" will also be used to refer to these Makai areas, though in fact Makai block information came primarily from HCDA (see Section 2.1.4);

[7] A consistent system was needed because HCDA used one set of numbers for the Existing database and a different set for the same blocks in what is here called the Future Baseline dataset.

3. KS Master Plan blocks, which all equate to VIA blocks, except for one VIA block that had to be *split* because only part of it was located within "Block B" of the KS Master Plan – these are a sub-set of HCDA Mauka blocks for which HCDA Future Baseline numbers were replaced by VIA estimates based on the KS Master Plan;

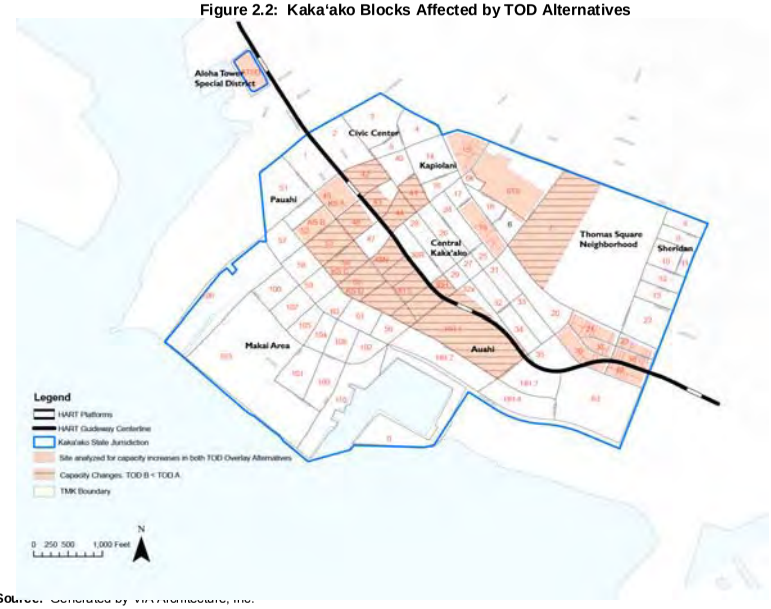
4. HH Master Plan blocks, which sometimes equate to VIA blocks but sometimes consist of an *aggregation* of those blocks and/or involve *splitting* VIA blocks – these are a sub-set of VIA Mauka blocks for which HCDA Future Baseline numbers were replaced by VIA estimates based on the HH Master Plan.

Because the KS and HH blocks (especially HH "Block 5" from its Master Plan) require these splits, the final geographical output had a few areas that were partial VIA blocks *not* absorbed into HH areas.

Figure 2.2 shows the VIA block numbering system. It also identifies the specific blocks (colored) assumed by VIA to have higher density for both TOD Alternatives – with hatched blocks having lower density under TOD Alternative B than under TOD Alternative A.

TOD-affected blocks include:

- Certain HH and KS blocks; and



- Blocks with various other owners – which will hereafter be called ***"Other TOD Blocks"*** to indicate non-HH, non-KS blocks assumed by VIA to be differently developed under the TOD Alternatives than under the Future Baseline Condition.

The following Table 2.1 indicates which major landowner blocks are assumed to change from the Future Baseline Condition to either of the TOD Alternatives (A or B). Table 2.2 provides a similar list of the "VIA Blocks" (non-KS and non-HH blocks assumed to change).

Table 2.1: Kamehameha Schools and Howard Hughes Blocks Affected by TOD

VIA Block No.	Source of Square Footage and Unit Assumptions (Future Baseline Condition and Both TOD Alternatives)	KS or HH Master Plan Block No.
45	**Future Baseline Condition:** VIA generated initial square footage assumptions based on landowners' Master Plans, including as appropriate information on projects in Phase 1 planning stages. JMK Associates finalized, and estimated units, based on procedures described in Section 2.1.4. **TOD Alternatives (A and B):** VIA generated estimates of potential additional development within the areas eligible for the TOD Plan, and JMK Associates finalized in same way.	KS Block A
52K (portion of original Block 52 equivalent to KS Block B)		KS Block B
54		KS Block C
55		KS Block D
62		HH Block 1
49, 50, 56 (all parts), part of 30 (called 30H), and part of 48 (48S)		HH Block 5

Figure 2.2: Kaka'ako Blocks Affected by TOD Alternatives

Source: Generated by VIA Architecture, Inc.

Table 2.2: "Other TOD Blocks" Assumed to Be Affected by TOD Development

VIA Block No.	Source of Square Footage and Unit Assumptions (Future Baseline Condition)	Source of Square Footage and Unit Assumptions (TOD Alternatives A and B)
6TS, 15, 19, 21, 36-39, 41, 42, 44, 46, 48N, 53	All of these from the HCDA dataset adapted for "Future Baseline Condition" purposes	Square footage from VIA; units estimated by JMK Associates based on procedures described in Section 2.1.5
7 (B+C)		As above, plus carry-over of McKinley High School information from Future Baseline data
43		As above, plus carry-over of one building from Future Baseline that appeared outside the specified redevelopment area

- The exception was the addition of a project that HCDA apparently missed in the initial "Existing" spreadsheets – Kamakee Vista, which the 2010 Census indicated had 227 units. We assumed each unit was 600 square feet (SF), + 13% for common areas, for an estimated total 153,906 SF.

- In all use of HCDA spreadsheets, we generated building total SF and units by summing individual building story figures from HCDA and then summing buildings to get block totals. Because HCDA had some rounding error in its figures, our building/block totals deviated slightly from their totals (which HCDA separately reported). We carefully compared results to ensure that the deviations were of negligible magnitude. In a very few cases (in the Sheridan area), the unit-count deviations were sufficiently great that we utilized the original HCDA building totals rather than just the sum of the figures for stories.

  (The reason for this procedure was to permit "apples-to-apples" checks of summed figures from one internal spreadsheet page to another.)

Makai Area (including Aloha Tower Special District Site)

- As previously noted, the original HCDA spreadsheets covered only the Mauka parts of Kaka'ako. In 2013, HCDA generated a partial list of major buildings and total SF for each Makai block. JMK Associates supplemented this with visual inspections (on-site and Google Earth) to produce a complete list of buildings, and then conferred with HCDA to generate additional square footage estimates for most or all of the remaining buildings. VIA also contributed to this inventory of existing uses.

- Two sites could <u>not</u> be translated into square footage estimates desired by Nelson\Nygaard for its traffic analysis:

- **Kewalo Basin** had a year 2010 population of 223, according to US Census, but no "residential" SF. (It is unclear where these people were actually living, as living aboard boats is not permitted.) Additionally, SF estimates for scattered government structures were unavailable. However, we informed Nelson\Nygaard of the harbor master's estimates of total jobcount.

- **HECO Power Facility** ("Aloha Tower Special District Site") – We could obtain only footprint SF info, not total SF, due to the odd nature of the building. Again, we informed Nelson\Nygaard of HECO's estimated total jobcount for the site.

2.1.4 Assumptions and Procedures for "Future Baseline Condition"

Mauka Area

- Initial data came from the HCDA dataset assumed to represent the "Future Baseline" – with addition of Kamakee Vista carry-over and block splits/reorganization as necessary for HH properties. As noted above and below, some original HCDA block data were then either (a) replaced by information generated by VIA, including adjustments for continued or redeveloped Industrial uses; or (b) in a few cases, supplemented by HCDA data for specific projects entitled since the original HCDA dataset was compiled. These cases were:

  - Symphony Honolulu (Block 6) – Assumed to be original HCDA Future Baseline 2035 Building #2. However, in 2013 HCDA provided updated square footage information replacing that for one building in the original database.

  - 801 South Street – Phases I and II plus reduction in total space for the existing historic News Building (Block 14). Project data provided by HCDA replaced all that contained in the original HCDA Future Baseline for Block 14.

- For the KS and HH blocks identified previously in Table 2.1, initial square footage inputs were provided by VIA based on landowner Master Plans. VIA also provided square footage inputs for the KS-owned Block 57 – which is not expected to be affected by TOD – to reflect Master Plan approvals obtained since the HCDA dataset was completed in 2010.

- These initial figures lacked some elements required by Nelson\Nygaard and/or JMK Associates, and so we adjusted or supplemented the VIA inputs as follows.

  - **Residential Unit Counts:** These were derived first by separately estimating Luxury, Market, and Reserved Unit[8] percentages and unit sizes, and then

[8] Under the current *Mauka Area Plan*, developers are required to "reserve" a certain amount – generally 20% of the total residential floor area – for "workforce housing," which means buyers able to afford housing priced for households earning up to 140% of the Area Median Income as defined by the U.S. Dept. of Housing and Urban Development. These "Reserved Units" remain at controlled prices for five years (if initially for sale) or 15 years (if initially for rentals), after which they may be sold at prevailing market rates. For further specifics, see Hawaii Administrative Rules, Chapter 15-218, Sept. 14, 2011,

calculating the weighted average unit size (adjusted to gross value by including common areas such as hallways). The total number of Residential SF estimated by VIA was then divided by this adjusted weighted average to yield unit counts. The assumptions used for this procedure are summarized in Table 2.3.

Table 2.3: Assumptions for Estimating Major Landowner Future Baseline Residential Unit Counts

	Luxury	Market	Reserved
% Distribution	35%	45%	20%
SF/Unit	2,000	1,100	850
Weighted Average Unit Size (SF, Net),* Calculated	1,365		
Assumed % of Total Residential SF for Common Areas	18%		
Weighted Average Unit Size (SF, Gross),* Calculated	1,665		

* Net excludes common areas such as hallways, lobbies, etc.; Gross includes them.
Source: Calculations by JMK Associates, based on input assumptions from HCDA, reflecting recent project distributions and square footages by unit type.

- **Non-Residential Land Use:** The initial VIA figures consisted of a single undifferentiated "Commercial" SF figure. Following the guidance of HCDA, JMK Associates allocated this VIA figure for each block as 70% Retail, 10% Office; and 20% Industrial.

- **Parking:** Consistent with VIA input, the number of stalls was calculated based on the following assumptions:

Table 2.4: Assumptions for Estimating Major Landowner Parking Stalls

Associated Use	No. of Parking Stalls
Individual Parking Stall Area	340 SF
Market Residential	1.35 / Unit
Reserved Residential	0.90 / Unit
Commercial	1 stall / 444 SF

Source: HCDA, 2005 *Mauka Area Rules*

- For non-KS and non-HH blocks, Residential unit counts were calculated as follows, on a building-by-building basis:

  - For Residential buildings that carried over from the Existing dataset, original HCDA unit counts were retained. And for the two entitled projects, developer-projected unit counts were maintained. The typical range of gross average unit sizes for these buildings was 900 to 1,000 SF.

  - For new Residential buildings, the original HCDA Residential SF estimate was divided by the gross weighted average unit size calculated in Table 2.3 above, as this figure was felt by HCDA to typify most recent projects.

http://dbedt.hawaii.gov/hcda/files/2013/02/Ch.-218-Kakaako-Reserved-Housing-Rules-EFF-2011-11-11.pdf.

- Following all the above steps, Block Total SF for Future Baseline were compared to similar SF totals for the Existing dataset. Some cases were found when the Future Baseline totals were less than for Existing, which should not occur. These discrepancies were resolved as follows:

  - Very small discrepancies (ca. 200 SF or less) were ignored, with the concurrence of HCDA, as being due to rounding procedures in the original data spreadsheets.

  - For two blocks (Kapi'olani Block 23 and Sheridan Block 9), original HCDA spreadsheets assumed redevelopment but had no parking. As per 2013 HCDA instructions, we allocated Existing Garage Parking SF numbers to new Future Baseline buildings that seemed closest in characteristics to the original buildings that did have parking.

- As a final step, the assumed total Future Baseline SF numbers for all KS blocks (aggregated) were compared to estimated entitled SF numbers for KS, and the same was done for HH blocks. The differences were negligible (under 1%) for KS, and became negligible for HH after the data were examined for accuracy and a few appropriate corrections were made, in consultation with VIA, to the final output.

Makai Area (including Aloha Tower Special District Site)

- VIA generated development assumptions for Makai blocks reflecting current Makai Rules. Except for the few blocks noted immediately below, VIA's initial input to this analysis assumed an undifferentiated "Commercial" square footage for each block that did not include parking numbers.

- JMK Associates followed VIA's assumptions that all Makai blocks would be redeveloped in this scenario – primarily for Office use, but also for a potential Presidential Library to house papers of President Obama – except the following, which would be carried over from the Existing dataset:

  - Block 100 (Gold Bond Bldg.);
  - Block 101 (Children's Discovery Center);
  - Parts of Block 103 (retaining JABSOM and a warehouse);
  - Block 105 (Gateway Park);
  - Parts of Block 106 (containing Re-Use Hawai'i and the Maritime Center).

  The above retained structures include some limited existing Industrial uses – no new Industrial is assumed for Makai areas.

- For other Makai sites (including the Aloha Tower Special District Site), JMK Associates followed VIA assumptions for redevelopment, with these additional steps:

  - With HCDA guidance and concurrence, we assumed VIA's "Commercial" square footage number for each block would be distributed as 20% Office and 80% Retail (no Industrial).

  - Because VIA output did not include parking, we estimated Garage Parking by applying a multiplier of (340/444 = 0.766) to VIA's total "Commercial." This was determined by a VIA-specified standard parking stall = 340 SF, and 1 parking stall/ 444 SF of commercial land use.

- As with the Mauka data, Block Total overall SF for Future Baseline were compared to similar totals for Existing. No blocks were found where the Future Baseline numbers were smaller than the Existing ones.

2.1.5 Assumptions and Procedures for TOD Alternatives A and B

The following procedures were used in the original 2013 analysis of TOD Alternative A and were then replicated exactly in 2014 for Alternative B (which was identical to Alternative A except for lower heights/densities in certain blocks designated by VIA).

Mauka Area

- Unless VIA assumed different development patterns for a geographical area under the TOD Alternatives than under the Future Baseline Condition, JMK Associates carried over the Future Baseline Condition figures to both of the TOD Alternative analyses. These were all blocks *except* those previously listed in Table 2.1 and Table 2.2.

- VIA generated TOD Alternative projections for TOD-affected KS and HH blocks – numbers larger than for the Future Baseline Condition – and also for the "Other TOD Blocks." Again, the VIA data lacked a few elements required by JMK Associates and/or Nelson\Nygaard, and these were estimated by JMK Associates through the same procedures and assumptions previously specified to generate additional information in the Future Baseline Condition, sometimes with certain exceptions as noted below:

  For the "Other TOD Blocks" (Non-KS and Non-HH):

  - **Residential Unit Counts:** Assumptions used to convert VIA total "Residential SF" into unit counts were identical to those in the foregoing Table 2.3.

  - **Non-Residential Land Use:** JMK Associates used VIA estimates for specified categories of Retail, Commercial/Office, Parking Garage, and Entertainment/ Other. The latter category consisted of possible Blaisdell redevelopment uses such as movie theaters, and for our purposes these "Entertainment" uses were simply added back into Retail.

  - **Parking:** For these blocks, VIA itself calculated parking square footage, which JMK Associates directly incorporated.

For the TOD-Affected KS and HH Blocks –

- o Residential unit counts through assumptions shown in foregoing Table 2.3, though applied to a larger potential development volume as estimated by VIA;
- o Distribution of VIA's initial generic "Commercial" square footage as 70% Retail, 10% Office; and 20% Industrial (again applied to a larger amount of space as estimated by VIA for the each of the TOD Alternatives);
- o Parking totals calculated for the assumed level of development under the Future Baseline were retained – however, VIA then estimated additional development permitted under the higher-density TOD Alternative Rules, and parking for the additional increments were calculated as per VIA's assumptions shown above in Table 2.4.

- Two potential Mauka-area hotels were assumed (in addition to one in the Makai area, as described below). While the proposed TOD Alternatives do not restrict the nature of potential hotels to the following description, these illustrative parameters were assumed for purposes of analysis (square footage from VIA, ensuing estimated number of units from JMK Associates):
  - o At the current Blaisdell complex site, a full-service hotel – for travelers desiring to stay outside Waikīkī – of 204,000 SF (434 units) for TOD Alternative A and of 167,371 SF (356 units) for Alternative B;
  - o In the Auahi Neighborhood Zone, a condo-hotel of about 104,000 SF (195 units) for TOD Alternative A and of 168,949 SF (317 units) for Alternative B. (Although overall densities were lower for selected blocks in Alternative B than Alternative A, this particular building was an exception in VIA's calculations.)
- Checks were again made to detect cases where the overall Block Total SF was improperly lower for the TOD Alternative than for the Future Baseline Condition. A few issues were identified that required attention from HCDA and VIA. In a few cases, JMK Associates was advised that the discrepancies were acceptable, and the remaining issues were remedied.

Makai Area (including Aloha Tower Special District Site)

- As per VIA assumptions, JMK Associates carried over "Future Baseline Condition" figures for all blocks except the Aloha Tower Special District Site.
- For the Aloha Tower Special District Site, we used VIA figures, which were complete in the sense of including parking and explicit breakdown of Office and ground-floor Retail.

VIA estimated development of total Residential square footage at the Aloha Tower Special District Site under the TOD Alternative A (which remained the same for Alternative B). We calculated residential unit counts using the same assumptions as set forth previously in Table 2.3.

- At the Aloha Tower Special District Site, which abuts Downtown Honolulu, a business hotel (175,000 SF, 372 units) was assumed for both TOD Alternatives.
- As with the Mauka data, Block Total overall SF for the TOD Alternatives were compared to similar totals for the Future Baseline Condition. After due checking and revisions, two blocks remained where the TOD Alternative numbers were smaller than the Future Baseline Condition ones. For one (portion of Block 48 not owned by Howard Hughes), the difference was small and VIA instructed us the apparent discrepancy was within acceptable range of error.

  For the Blaisdell redevelopment site (Block 7B+C), differences were larger, but HCDA instructed us that the differences were still acceptable, reflecting possible future lower density.

2.2 Estimated Kaka'ako-Specific Population – Methods and Assumptions

Methods for estimating population (Chapter 4) are simpler to explain in concept, though the actual analysis was greatly complicated by the differences in building types for the three scenarios, with some buildings surviving, some buildings changing, and some future block data available only at aggregated rather than building-specific levels.

2.2.1 Types of Populations Studied

Two basic categories of population are estimated:

1. Full-time residential; and
2. De facto (number of people actually present *in units* on an average day – excludes an unknown and exceedingly difficult-to-estimate number of customers for retail and restaurant operations, which could vary greatly by time of day).

De facto population has three components:

- Full-time residents actually present (i.e., the full-time residential population *minus* those temporarily absent on vacations, business trips, etc.);
- Part-time residents, who are expected to comprise a somewhat larger percentage of the Kaka'ako population in the future as high-rise development offers more amenities such as ocean views and proximity to both downtown and Waikīkī); and

- Visitors staying in the three hotels with the Kaka`ako District envisioned by HCDA and VIA for this analysis.

2.2.2 General Locations Where Population Can Stay or Reside

Population is associated with Residential land uses – or, in the case of visitors, Hotel uses. These are confined to:

- The Mauka portion of Kaka'ako, not the Makai lands (except for the small Kewalo Basin population not associated with any housing units).

- For both TOD Alternatives (but not the Future Baseline), the Aloha Tower Special District Site is assumed to have residential development.

2.2.3 General Approach to Population Estimates

Initial Step: For any particular location or structure with Residential or Hotel uses, determine: (a) Total number of units; and (b) Whether structure is for Residential use or Hotel use. (No mixed residential-visitor uses are permitted under current or proposed new Rules, so all structures with population would be either one or the other.)

For Residential-use structures, further determine (c) Percentage held for part-time use; and (d) Percentage occupied full-time. Remaining units are (e) considered vacant and available for full-time use. Then (f) occupancy factor for full-time residents would equal available vacant units divided by (full-time occupied + available vacant units).

Population Calculations: Table 2.5 shows how to calculate various population types associated with residential housing or visitor units.

Table 2.5: Logic of Population Calculations

Population Type =	Units/Base		Occupancy %		Household Size
A. Full-Time Residential Population =	No. Residential Units Not Held for Part-Timers	x	Occupancy Factor for Full-Time Residents	x	Average Household Size (AHHS) for Full-Time Residents
B. De Facto Population =	*(Sum of Three Components Below)*				
• Full-Time Residents Actually Present	Population Computed in (A)	x	(100% - Avg. % Off-Island)		
• Part-Time Residents Actually Present	No. Residential Units Held for Part-Timers	x	Avg. % of Year Part-Timers Present	x	AHHS for Part-Time Residents
• Average Visitor Count	Total Hotel Units	x	Avg. Occupancy for That Type of Hotel	x	Average Party Size for That Type of Hotel

For purposes of this analysis, decisions were first made as to whether the required input parameters could vary *by place* (i.e., are "place-specific" and thus more accurate) within Kaka'ako or would be fixed across all locations. Census data permit some assumptions

to be very place-specific within Kaka'ako, but place-specific data are not available for other parameters; data sources for them are more general and therefore fixed across all Kaka'ako locations. For hotels, the question is less whether the variation is by area than by type (e.g., traditional full-service resort hotel vs. condo-hotel). See Table 2.6:

Table 2.6: Whether Population Parameters Are Fixed or Could Be Place-Specific

	Full-Time Residential	De Facto: Full-Time Residential Component	De Facto: Part-Time Residential Component	De Facto: Visitor Component
AHHS	Place-Specific*	N/A	Fixed Over Areas	Both Specific to Hotel Type
Occupancy	Place-Specific*	Fixed Over Areas	Fixed Over Areas	

* More accurately: *Possibly* Place-Specific. Kaka'ako-wide numbers were used as a back-up option in certain cases where place-specific parameters could not be determined from Census data. This proved to be the case in a number of situations – see Section 2.2.5.

At the same time, decisions were made as to whether population parameters for this analysis would vary *by time* (i.e., Existing, presumed to be 2010, versus Future Baseline Condition and/or TOD Alternatives, all of which future scenarios are presumed to reflect 2035 build-outs under different Rules). As explained in the next section, most were fixed over time – see Table 2.7:

Table 2.7: Whether Population Parameters Vary by Time or Remain Fixed

	Full-Time Residential	De Facto: Full-Time Residential Component	De Facto: Part-Time Residential Component	De Facto: Visitor Component
AHHS	Fixed Over Time	N/A	Fixed Over Time	N/A; Only Future Values Are Used
Occupancy	Fixed Over Time	Fixed Over Time	Fixed Over Time	

2.2.4 Population Parameters with Fixed Values in This Analysis

Specific Residential Values: Table 2.8 presents specific assumed values and sources for parameters fixed by both place and time.

Table 2.8: Values for Population Parameters Fixed Over Both Place and Time

	Existing	Future	Source	Comments
% Full-Time Residents Actually Present*	94.5%	94.5%	"State of Hawaii Data Book Timeseries" http://hawaii.gov/dbedt/info/economic/databook/Data_Book_time_series/ Accessed March 4, 2013	Future figure kept constant for purposes of conservative analysis -- will in reality be affected by travel prices.
Part-Time Resident Average HH Size	2.14	2.14	Weighted average of estimates from Kaka'ako condominiums gathered in survey by JMK Associates, Jan. - Feb. 2013.	Lack of trend data requires assumptions fixed over time.
Part-Time Resident Occupancy	39.0%	39.0%		

* Equivalent to "Occupancy" for "De Facto: Full-Time Residential Component" in Table 2.6.

Residential Values That May Vary by Place but Remain Fixed Over Time: While assumed full-time residential AHHS and occupancy rates may vary by location – i.e., are possibly "Place-Specific" in Table 2.6 – they are assumed in Table 2.7 to remain the same for any particular location in the Existing vs. Future Baseline Condition or TOD Alternatives (A or B). This assumption of lack of change over time is a critical one, particularly for AHHS. A future decrease in household size could mean less population even if the number of occupied residential units remained constant.

In fact, household sizes in the City and County of Honolulu overall had fallen in each decennial Census – *until* the 2010 Census, when they held steady and even very slightly increased, from 2.95 to 2.96. This may reflect the intensifying pressures on the Hawai'i housing market, which is one of the most expensive in the nation. Figure 2.3 shows the trend analysis along with three possible trend lines extrapolated to the future: a linear trend, a 2nd-order polynomial trend, and a 3rd-order polynomial trend line.

Figure 2.3: Historical Data on Honolulu County Household Sizes

Note that what is being established here is not the actual value of the average household size for any place within Kaka'ako, which will be addressed in the following Section 2.2.5, but rather the principle that whatever 2010 value is used for a particular place in Kaka'ako will remain constant in the future. That decision to hold place-specific AHHS constant over time for various locations within Kaka'ako reflects:

1. A compromise among the greatly differing trend extrapolations in Figure 2.3, with the flat line from 2000 to 2010 considered the best available *recent* trend;

2. The principle in EIS work that estimates should err, if at all, on the conservative side – a lower AHHS would mean less population and so the decision not to assume future declines results in a larger and thus more conservative estimate; and

3. The HCDA's emphasis on attracting families to Kaka'ako, which would mean a countervailing force to what might otherwise be an argument for a decreasing household size – i.e., the aging of the overall population, resulting in expectations of lower household sizes, particularly in dense urban areas.

Hotel Population Parameters for the TOD Alternatives: HCDA requested inclusion within this analysis of three different hotel types – (1) a traditional full-service hotel for travelers desiring to stay outside Waikīkī; (2) a condominium-hotel (which usually has significantly fewer guest amenities); and (3) an urban business hotel (which would usually have lower occupancy levels and lower party sizes, as fewer family members accompany business guests). A "business hotel" of course could also be patronized by *kama'āina* from other islands or even out-of-state leisure travelers, but if it is primarily aimed at the business traveler, it would likely have somewhat fewer amenities than a traditional resort hotel.

Although no hotels are in the "Existing" dataset of Kaka'ako structures, determining the future parameters for calculating the visitor population requires estimating a reasonably correct "Existing" value and then making judgmental assumptions about future values. Table 2.9 and Table 2.10 show assumed values and sources/rationales for the two key input parameters of average party size and hotel occupancy level.

Table 2.9: Visitor Population Parameters by Hotel Type – Average Party Size

Hotel Type	Existing*	Future	Source	Comments
Full-Service Hotel for Travelers Wanting to Stay Outside Waikīkī	2.20	2.35	Based on examination of "Hotel-Only" party size from various *Annual Visitor Research Reports***	Party size increasing as hotel rates rise, which is assumed to continue due to limited supply as demand increases.
Condo-Hotel	2.31	2.55	Based on examination of "Condo-Only" party size from *Annual Visitor Research Reports***	Party size also increasing over time, and likely to keep doing so as hotel rates force larger parties into condos.
Business Hotel	1.70	1.80	Based on examination of "Meetings, Conventions, Incentive" (MCI) party size from Annual Visitor Research Reports.	Hawai'i has no real pure business hotel now. MCI party sizes reflect Waikīkī situation; non-Waikīkī locations would attract fewer families.

* Not directly used in this analysis, but indirectly used as basis for assumed future value.
** Now prepared by Hawai'i Tourism Authority, formerly by Hawaii State Dept. of Business, Economic Development and Tourism (DBEDT). See http://www.hawaiitourismauthority.org/research/reports/.

Table 2.10: Visitor Population Parameters by Hotel Type – Occupancy Level

Hotel Types	Existing*	Future	Source	Comments
Full-Service Hotel for Travelers Wanting to Stay Outside Waikīkī	78.0%	82.0%	*Annual Visitor Research Reports.* 78% = O'ahu average during 2002-07 economic cycle (and 10-year average from 2002 to 2011 almost as high).	Assumed to rise in future because of increasing demand relative to supply. Peak Waikīkī occupancies actually higher now due to international demand, but this could reflect transient exchange rate situation.
Condo-Hotel	70.0%	74.0%	No published data formally available; estimates based on opinions of hotel experts contacted by JMK Associates.	
Business Hotel	68.0%	70.0%		

* Not directly used in this analysis, but indirectly used as basis for assumed future value.

2.2.5 Residential Population Parameters Assumed to Be Place-Specific in Kaka'ako

Parameters and Census Equivalents: For this analysis, three final population parameters varied by area (i.e., were "place-specific") within Kaka'ako, with various final assumptions ultimately derived from the 2010 U.S. Census. These were –

1. Percentage of units in residential buildings for part-time residents;

2. Percentage of remaining units in residential buildings vacant – i.e., adjusted vacancy factor used to determine "occupancy factor for full-time residents" (Table 2.5);

3. Average household size (AHHS) for full-time residents.

For each of these, the Census provides *block-level* data for GEOID codes ("GEOIDs").[9] These GEOIDs, mostly though not perfectly, correspond to the VIA blocks used for this analysis. Specifically, the Census provides the following place-specific information used to generate assumptions for the above three parameters –

1. Percentage of housing units "vacant," with vacancies allocated to different categories. One vacancy category is "Held for Seasonal, Recreational, or Occasional Use" (SROU). This would usually mean part-time residential use.

2. Total vacant units *minus* the SROU vacant units would generate the adjusted vacancy level used to determine "occupancy factor for full-time residents."

[9] GEOIDs are the basis of the worldwide numbering system for land areas; they are used to link data series to particular land areas. The U.S. Census creates GEOIDs by stringing together numbers for the State FIPS (Federal Information Processing Standard) code, the county FIPS code, the Census tract code, and the Census block code. For example, VIA Block 46 has a GEOID of 150030038003007. In the Census numbering system, the code for Hawai'i is 15; the code for City and County of Honolulu is 003; the code for the relevant Kaka'ako Census Tract is 003800; and the block identifier is 3007.

3. Total population in households divided by total occupied full-time residential units provides an Average Household Size factor (AHHS).[10]

This place-specific *block-level* 2010 data provided an initial basis for developing assumed values for the three population parameters under discussion here. It did not necessarily provide a final basis because the 2010 values for any particular GEOID block would logically depend on the mix of building types present on that block. This mix might change in the future scenarios. Therefore, it was ultimately necessary to generate *building-level* values for each of the three parameters by general area within Kaka'ako.

A final small place-specific population involved the only population for Makai lands – Kewalo Basin (Census count of 223 in 2010, held constant in all future scenarios).

Census 2010 Versus HCDA Existing Database: Before the procedures for generating the building-level values are explained, it is useful to note there were substantial differences between the 2010 Census housing unit count and the number of units generated by HCDA in 2009 for the "Existing" Database.

For some parts of Kaka'ako, the Census found more units than reported in the HCDA Existing dataset, but overall HCDA had 36% more residential units than the Census reported for the following year. The pattern by Neighborhood Zone suggests the Census found more units in low- to mid-rise areas, while HCDA found more in high-rise areas (Table 2.11).

Table 2.11: Housing Unit Estimates – 2010 Census Versus HCDA "Existing"

	HCDA "Existing"*	2010 Census
Sheridan Neighborhood Zone (N.Z.)	431	461
Thomas Square District N.Z.	554	442
Civic Center N.Z.	185	242
Kapi'olani N.Z.	2,426	1,454
Central Kaka'ako N.Z.	509	1,201
Auahi N.Z.	3,004	1,326
Pauahi N.Z	1,221	1,005
Makai + Aloha Tower Special District Site	0	0
KAKA'AKO TOTAL	**8,330**	**6,131**

* These HCDA unit counts are based on sums of units for each building story in the original database, prior to adjustments described in Section 2.1.4, such as the addition of the Kamakee Vista project, which occurred as a result of this comparison of Census and HCDA numbers. The final unit count for the adjusted HCDA "Existing" database for this analysis was 8,619.

While the Census takes care to train its workers carefully, experience has shown it is not a perfect procedure either. JMK Associates cannot judge which set of numbers is

[10] The Census also provides data for Total Population including those *not* in households. The Kaka'ako-wide Total Population was about 5% greater than the Population in Households as of 2010. The difference was primarily due to (a) temporary group quarters/shelters located in the Civic Center Neighborhood as of 2010, since gone; and (b) live-aboard population at Kewalo Harbor. The first group can safely be ignored for future population projections, while the 223 population for Kewalo was held constant for both the Future Baseline and also the two TOD Overlay Alternatives.

more accurate for the "Existing" situation. In most ways, ***this discrepancy is irrelevant for this impact assessment, which is ultimately based on the difference between the Future Baseline Condition's and the two TOD Alternatives' (A or B) numbers.***

However, because the Future Baseline numbers come substantially from the corresponding HCDA projections for build-out under current Rules, and because the HCDA Existing database goes to the building level (which the Census does not), JMK Associates necessarily chose to:

- Build "Existing" scenario results on HCDA rather than Census unit counts; but
- Apply 2010 Census-based parameters such as Average Household Size to the HCDA units for *all* scenarios – Existing, Future Baseline, and TOD Alternatives A and B.

Procedures for Developing Place-Specific Population Parameters at the Building Level: These procedures assign values for the three place-specific parameters – percentage of units for part-time residents, adjusted residential occupancy, and AHHS – as a function of (a) location, and (b) building type. The procedures were as follows:

1. Assemble a candidate list of residential "Building Types" for which parameters theoretically might differ. This initial list consisted of:
   - Generic low-rise buildings (1 to 3 stories);
   - Generic mid-rise buildings (4 to 11 stories);
   - Generic high-rise towers (12+ stories);
   - Luxury towers;
   - Workforce housing;[11]
   - Elderly housing.
2. For the Existing scenario, determine which blocks are
   - "Uniform" in the sense of consisting entirely of residential buildings that are of only one of the foregoing Building Types. Further specify if this is "Uniform Low-Rise," "Uniform High-Rise," etc.
   - "Mixed," in the sense of consisting of different types of residential buildings.

   The reason for doing this is that Census GEOID values for a Uniform block can reasonably be applied to all buildings on that block. For example, if the AHHS value is, say, 2.13 for a Uniform block, it is reasonable to use the 2.13 value for each

[11] As defined in the 2011 Mauka Area Rules, §15-218-16, a workforce housing project "means new residential project(s) where at least seventy-five percent of the residential units are set aside for purchase by families earning between one hundred to one hundred forty percent of the [Area Median Income], which does not require assistance from … governmental bodies, and which meets the size requirements set forth" elsewhere in the chapter.

building on the block – similar buildings in the same location may be assumed to have the same household sizes. But if the block is Mixed, this combined 2.13 value is much more likely to be an average of very different values for different buildings.

3. Determine Census GEOIDs that (a) corresponded well with original HCDA blocks (prior to any splitting of those blocks that may later have been required); and (b) are Uniform in a particular way from the preceding Step #2. When one or more such cases occurred, also compute for each building type a weighted average for the Neighborhood Zone (i.e., Sheridan, Auahi, etc.) and for Kaka'ako as a whole.

   There are two reasons for doing this:
   - The first is to aid in decisions about which of the initial candidate "Building Types" have distinctive values for the various population parameters and which have sufficiently similar values to other buildings that they can be dropped from the list.
   - The second is to assist in developing "Principles" that will dictate what population parameter values are to be applied to different building types in Mixed blocks and/or to future scenarios where density increases greatly.

   The remaining steps below also contribute to both of these two purposes.
4. For "Building Types," use information from the above steps to determine if the more specialized types of buildings under consideration – luxury towers, workforce housing, elderly housing – had sufficiently unique characteristics (when compared to other buildings of similar heights) to justify retaining them on the list. If some types are dropped, then repeat steps #2 and #3 with the revised list, as there may now be fewer blocks that would be considered Mixed and more that would be Uniform.
5. For "Principles," determine if variation across places within Kaka'ako was sufficient to justify use of place-specific population parameters or if the differences were so minimal that Kaka'ako-wide averages might as well be applied. For these Principles, "place-specific" would mean *Neighborhood Zone* weighted averages, rather than the values for given blocks. That is because the Principles are, for the Existing scenario, primarily for the purpose of applying to buildings within Mixed blocks only, where block values cannot be applied to each building.

   If some Neighborhood Zones have no Uniform blocks from which values can be derived, finalize the Principles for Mixed blocks by using values from contiguous Neighborhood Zones.
6. Finally, for the Future Baseline Condition and both TOD Alternatives (A and B), determine for each block:
   - If it is Uniform in a particular way for the Existing situation, is it Uniform in the same way in future (e.g., is a Uniform Low-Rise block ca. 2009/2010 still

projected to be a Uniform Low-Rise block in 2035, whether or not the residential buildings appear to be identical)?

- If it is Mixed for the Existing situation, do the exact same residential buildings carry over into a future scenario, with no additional residential construction?

The reason for doing this is that these are conditions under which the 2010 Census values for AHHS, etc. can appropriately be used again in the future. The "Principles" are for the purpose of assigning population parameters in future situations where these conditions do *not* apply.

Place-Specific Parameters Developed from These Procedures: The procedures described above resulted in these outcomes –

1. ***Final List of Building Types Used in Analysis:*** From the initial candidate list, these categories survived:

   - Generic low-rise buildings (1 to 3 stories);
   - Generic mid-rise buildings (4 to 11 stories);
   - Generic high-rise towers (12+ stories);
   - Elderly housing.

   Blocks consisting of workforce housing projects did not have distinctive AHHS or residential population parameters compared to other nearby buildings of similar heights. This simply suggests that Kaka'ako households of lower incomes have similar household sizes as higher-income households, despite likely smaller unit sizes. In a suburban area, this might not be true, as people who can afford larger homes might be at a stage of their lives where they have larger families. However, it proved true in Kaka'ako. Workforce projects *did* have expectably lower (and almost negligible) percentages of units for part-time residents (what the Census termed "vacant" but held for "Seasonal, Recreational, or Occasional Use," SROU). But as no known pure workforce towers are planned for the future, this issue could be resolved by having a second set of Principles only for the SROU parameters; existing workforce projects would not use these, but would use actual Census data.

   Known luxury towers differed from other high-rises mostly in terms of the percentage of units apparently held for part-time use (SROUs). These variations in SROU proved a function of location – towers in certain areas are more likely to be developed with amenities and available views that appeal to part-time residents. So by developing a separate set of Neighborhood-specific Principles just for this parameter, it was no longer necessary to specify "luxury tower" as a separate Building Type – that will be effectively accomplished by noting the location.

2. ***Final Principles for Estimating the Population Parameters when 2010 Census Block Information Cannot Be Used:*** The "Principles" apply to Mixed blocks, existing and future, and to much greater future densities. As noted, two separate

sets of Principles were developed, one for % of SROU/part-time units, and another for AHHS and adjusted full-time residential vacancy after subtraction of SROU units.

For the most part, examination of Census data suggested that Kaka'ako-wide values could be used. The exception was SROU/part-time units for high-rises (following Table 2.12). Note there are a few areas in which Principles do not apply due to non-development.

However, for adjusted vacancy rates and AHHS, the values are applied to all Neighborhood Zones under the Principles. Again, these values are for cases when the 2010 Census values cannot logically be used – primarily Mixed blocks.

Table 2.12: Principles for Assigning Percentage of Units to Part-Time Use

Neighborhood Zone	High-Rise	Mid-Rise	Low-Rise	Elderly[a]
Sheridan	N/A	3.0% for all areas	0.5% for all areas	0.0% for all areas
Thomas Square District	3.6%			
Civic Center	4.0%[c]			
Kapi'olani	6.9%			
Central Kaka'ako	11.7%[d]			
Auahi	29.8%			
Pauahi, *below* Pohukaina St.[b]	10.8%			
Pauahi, *above* Pohukaina St.[b]	1.1%			
Makai	N/A	N/A	N/A	N/A
Aloha Tower Special District Site (Both in TOD Alternative A and in TOD Alternative B)	29.8%	N/A	N/A	N/A

[a] Applies to just two buildings in Existing dataset, only one of which survives in future scenarios.
[b] As SROU percentage likely reflects views, it was necessary to split Pauahi, which has a substantial portion located nearer the ocean and another portion farther from the ocean.
[c] Based on average of nearby Neighborhood Zones.
[d] This figure excludes SROU percentages from workforce projects, which would not apply in future.

Table 2.13: Principles for Assigning Values of Adjusted Vacancy Rates and Average Household Size

	High-Rise	Mid-Rise	Low-Rise	Elderly[a]
Vacancy Rates, All Areas	4.73%	4.32%	4.41%	0.0%
Avg. Household Size, All Areas	1.98	1.40	2.22	1.18

[a] Elderly value applied to surviving Pohulani building in future, after additional development creates a Mixed block that still includes that project.

2.2.6 Final Population Calculation Procedures

Full-Time Residential Population and Residential Components of De Facto – Existing Scenario

1. For the Existing scenario, start with the number of units in each building and each block to complete the following steps.

2. For each building in each block, use the basic logic in Table 2.5, with appropriate specific values as follows for various Building Types.

3. For each Building Type in each block, use the specific population parameter values as follows (following Table 2.14), according to whether it is a Uniform or a Mixed block.

4. For each population type – full-time residential and the residential components of de facto population – sum the building populations to get total block populations. Sum the block populations to get Neighborhood Zone populations. Sum the Neighborhood Zone populations to get Kaka'ako-wide populations for the Existing scenario.

Table 2.14: Final Procedures for Residential Population Calculation (Existing)

	Uniform Blocks	Mixed Blocks
% Units for Part-Time (SROU) Use	Block-specific 2010 Census values	Appropriate value from Table 2.12
Adjusted Occupancy Factor for Full-Time Residents		100% minus appropriate value from Table 2.13
Avg. HH Size for Full-Time Residents		Appropriate value from Table 2.13
Avg. HH Size for Part-Time Residents	Appropriate values from Table 2.8	Appropriate values from Table 2.8
Occupancy Factor for Part-Time Residents		
% Full-Time Residents Actually Present		

Full-Time Residential Population and Residential Components of De Facto – Future Baseline Condition and the TOD Alternatives (A and B)

1. For each of the three future scenarios, repeat Steps #1 to #3 listed immediately above for the Existing scenario. *However*, also apply the specific population parameters developed in the "Principles" exercise not only to Mixed blocks but also to "Uniform" blocks that have changed profiles compared to their "Existing" condition.

   That is, if an "Existing" block with a Uniform profile of one density type (such as all Low-Rise) for a future scenario has a Uniform profile of a different type (such as all High-Rise), then it is no longer appropriate to use block-specific 2010 Census values. It is only appropriate to use the 2010 Census values for things like average household size if the block was Uniform in 2010 and is still Uniform in the same way for the future scenario. Thus, the logic of Table 2.14 is slightly modified when applied to the future scenarios (Table 2.15):

Table 2.15: Final Procedures for Residential Population Calculation (Future Baseline Condition or TOD Alternatives A and B)

	Blocks That Are Uniform in Same Way They Were Uniform in Existing Scenario	Blocks That Are Mixed or Uniform in Different Way Than They Were Uniform in Existing Scenario
% Units for Part-Time (SROU) Use	Block-specific 2010 Census values	Appropriate value from Table 2.12
Adjusted Occupancy Factor for Full-Time Residents		100% minus appropriate value from Table 2.13
Avg. HH Size for Full-Time Residents		Appropriate value from Table 2.13
Avg. HH Size for Part-Time Residents	Appropriate values from Table 2.8	Appropriate values from Table 2.8
Occupancy Factor for Part-Time Residents		
% Full-Time Residents Actually Present		

Note: Blocks for which VIA provided new square footage estimates on an aggregate basis, without specifying individual buildings, have all been categorized as "Uniform High-Rise." It is possible that some actual future structures on these blocks may be low- or mid-rise elements wrapped around towers, but the assumption is that such cases will usually involve master-planned city blocks that effectively function as a single integrated structure, and the high-rise tower components would dominate the basic character of the blocks.

2. For each population type – full-time residential and the residential components of de facto population – again sum the building populations to get total block populations. Sum the block populations to get Neighborhood Zone populations. Sum the Neighborhood Zone populations to get Kaka'ako-wide populations for the Future Baseline Condition and both TOD Alternatives.

3. For full-time residential population, subtract Future Baseline populations from populations for each TOD Alternative to get "impact" of each TOD Alternative.

Visitor Population Component of De Facto Population (TOD Alternatives Only) and Total De Facto Population (All Scenarios)

1. For each TOD Alternative, start with the number of units in each Hotel type and complete the remaining steps.

2. For each Hotel Type, use the basic logic at bottom of Table 2.5, with appropriate specific values for various Hotel types from Table 2.9 and Table 2.10 to get visitor populations for hotel structures.

3. In all scenarios – Existing, Future Baseline, and both TOD Alternatives – sum the various components of de facto population (full-time residents actually present, part-time residents present, visitors present) to get total de facto for each block.

   Sum the block de facto populations to get Neighborhood Zone de facto populations. Sum the Neighborhood Zone de facto populations to get Kaka'ako-wide de facto population.

4. For total de facto population, subtract Future Baseline Condition figures from similar figures for each TOD Alternative figures to get "impact" for de facto population for each TOD Alternative (A or B).

2.3 Estimated Kaka'ako-Specific Operational Employment – Methods and Assumptions

"Operational employment" (results in Chapter 5) means jobs associated with operating businesses, as opposed to "Construction employment," methods for which are described in the following Section 2.4.

2.3.1 Types of Operational Jobs Studied

Consistent with typical economic impact procedures, combined direct jobcounts (full- and part-time) are estimated. These are a sum of jobs associated with each of the following specific uses previously calculated through the methods described in Section 2.1:

- Residential (e.g., building managers, maintenance, security)
- Hotel
- Civic/Public (includes Children's Discovery Center)
- Office
- Retail
- Industrial
- Surface Parking
- Garage Parking
- JABSOM, in the Makai area

Following discussions of methods and assumptions for statewide/islandwide impacts (Section 2.6 and Section 2.7) will distinguish between "direct" jobs and "total" jobs with economic multiplier effects. For purposes of analyzing Kaka'ako-specific operational jobs – as well as the subsequent discussion of Kaka'ako-specific construction employment – ***only direct jobs are considered.*** That is because it is appropriate to include multiplier effects only for those project components that would not otherwise occur somewhere on the island without the proposed project. The subsequent islandwide analysis includes such multiplier effects, but the Kaka'ako-specific analysis does not.

2.3.2 General Approach to Kaka'ako-Specific Operational Employment Analysis

Calculation Procedures: There were two general approaches –

1. For the great majority of instances, jobs were calculated as a product of the square footage for a particular use (e.g., Office or Retail) times an assumed employment multiplier (jobs per 1,000 SF) specific to that use. For Residential and Hotel uses, the multipliers were in terms of jobs per unit. As explained shortly, use-specific multipliers differed for each future build-out scenario (Future Baseline Condition and the TOD Alternatives A and B) from those used for the Existing Scenario calculations.

2. For a few instances relating to existing activities, known job numbers could be identified, based on information from the respective agencies: (a) The existing HECO power plant at the "Aloha Tower Special District" had a current jobcount of about 40 in 2013. The facility has since been placed on standby basis, but is projected for redevelopment under all future scenarios. (b) JABSOM currently has a jobcount of 240, and the School does not expect changes in the future. (c) Kewalo Harbor officials estimate the current jobcount (including concessionaires) as about 200, and believe it could grow to 250 in the future.

Labor Productivity and Implications for Future-Scenario Multipliers: Due to technology and other labor-saving innovations, fewer workers are generally needed over time to achieve the same level of economic output. This is recognized in the State Input-Output (I-O) Model, which uses year-specific multipliers that forecast fewer jobs over time for the same level of sales.

Unlike the I-O methodology (described in following sections and used for other parts of this study), which is based on dollar output, the appropriate approach for this operational-job component involves multipliers based on jobs per SF or jobs per unit – i.e., physical size of the economic activity. Productivity over time can have differing effects on different spatial job multipliers that apply to different economic activities:

- For many or most uses, the required space for a given level of economic activity is *fixed*, and the implication is that future jobs per 1,000 SF will be less than at present. For example, a grocery store or a restaurant requires a certain amount of space, and so labor-saving technology implies future job multipliers will be *lower*.

- Office space, however, is different.[12] As the number of employees required for the same level of economic activity shrinks, *and* the space needed for each worker

[12] For this study, we regard *only* Office uses as different in the sense of appropriately requiring a higher rather than lower multiplier in the future. In theory, some types of Civic/Public uses might similarly be affected, but major Kaka'ako examples such as McKinley High School or government office buildings are more similar to restaurants and grocery stores, in that they do not have the option to move into smaller spaces when increased labor productivity results in demand for fewer employees.

declines due to technology (e.g., less physical file storage needed), businesses simply lease less space. This means that future job multipliers will be *higher*.

In practice, it also means that demand for Office space is slowing, and that the sort of Office space projections contained in both TOD Alternatives (or, to an even greater extent, the Future Baseline Condition) may in practice be very unlikely to materialize by 2035. This part of HCDA's vision may well require more time to materialize.

Fixed vs. Place- or Building-Specific Employment Multipliers: As with population parameters, a decision was required whether to keep job multipliers fixed for all parts of Kaka'ako or assume different multipliers for different places or different building types. As described shortly, most were fixed, making for a simpler analytic procedure.

2.3.3 Operational Employment Multipliers with Fixed Values in This Analysis

Except for jobs associated with Residential and Hotel buildings (see following Section 2.3.4), all multipliers were fixed across Kaka'ako. Table 2.16 shows the multiplier values applied to square footage for the six land/building use categories using that method, and briefly notes the basis of the *Existing* Scenario values. The immediately following discussion explains the basis for estimating the three *Future* scenario values.

Table 2.16: Employment Multipliers Per 1,000 Square Feet for Various Uses

	Existing	Future	Source / Comments
Civic/Public	2.500	2.059	City multipliers for these categories were developed based on 1990 data but have not since been updated. JMK Associates updated to 2010 ("Existing") based on a review of about a dozen studies and planning guides.* Updated values maintained roughly the same internal ratios among the four multipliers from the City's original study of the early 1990s.
Office	4.000	4.545	
Retail	2.000	1.642	
Industrial	1.667	1.397	
Surface Parking	0.042	0.034	"Existing" based on calls to Hawai'i parking garages and a national planning guide.
Garage Parking	0.017	0.014	

* Most of the available literature was not Hawai'i-specific, but a few – including Hawai'i Retail numbers from the International Council of Shopping Centers – were specific to Hawai'i.

The Future values in the table above (for the Future Baseline Condition and both TOD Alternatives A and B) were developed as follows:

- For the Civic, Retail, and Industrial categories, the City's 1990 values were taken as a baseline, and the average annual growth rate between each 1990 value and the assumed 2010 value was calculated. This average growth rate was used to project a 2035 ("Future") value. These average growth rates were between -0.7% and -0.8%.

- The Garage Parking 2010 value was then projected to the future using a -0.75% average annual growth rate, based on the above. Surface Parking, a very minor category in the future when little is assumed to be left, was assigned an average annual growth rate of -0.85%, resulting in just one future job.

- As per above discussion, the Office category was the only one for which the multiplier was to be assigned a positive growth rate. The future value was assumed on a more judgmental basis, with a slower growth rate of +.60%, to restore it to the approximate level of the City's multiplier for 1990.

2.3.4 Operational Employment Multipliers Assumed to Be Building-Specific in Kaka'ako

Residential: The number of jobs associated with managing or maintaining Residential complexes is relatively small, but the large total amount of new Residential structures envisioned under the Future Baseline Condition and (especially) the two TOD Alternatives A and B justified outreach to various building and property management firms for current structures in Kaka'ako and elsewhere in urban Honolulu. Based on these interviews, it was apparent that *job ratios vary with the level of amenities* for the building – e.g., more jobs per unit for luxury condominium projects.

Thus, the first step was to generate assumed multipliers for multi-unit Residential structures with varying amenity levels:

Table 2.17: Employment Multipliers Per Unit for Residential Structures

Amenity Level	Existing	Future	Source / Comments
High	0.025	0.021	Based on information from Kaka'ako and Urban Honolulu property managers. Future values were estimated at 82% of current values, reflecting typical declines in other multipliers listed above in Table 2.16.
Mid	0.060	0.049	
Low	0.100	0.082	

The next step was to decide which buildings in the various datasets should be considered to have high, mid, or low amenity levels. It is extremely difficult to forecast future amenity level for each structure in the build-out of all projects in all parts of Kaka'ako. The HCDA encourages as much affordable housing as possible, while many landowners/developers see more market opportunities at a higher end during certain portions of the economic cycle.

Therefore, the strategy taken was to effectively generate a variety of amenity levels by linking the assumed amenity level to the projected level of part-time residents (per discussion in foregoing Section 2.2.5, Table 2.12), as higher-amenity projects tend to attract higher proportions of off-shore buyers. The linkages assumed were:

Table 2.18: Linkage Between Residential Job Multipliers and Part-Time Residents

Amenity Level	Percentages of Part-Time Residents
High	20% or higher
Mid	10.1% to 19.9%
Low	10% or lower

Because this approach is building-specific, the allocation of assumed amenity levels did not end up neatly corresponding to particular Neighborhood Zones within Kaka'ako, but high-amenity structures tended to be concentrated in the Auahi and Aloha Tower Special District areas, while areas such as the Sheridan Neighborhood Zone were generally assumed to have low-amenity buildings both now and in the future. Mid-amenity buildings were most often assumed for parts of Pauahi, Central Kaka'ako, and Kapi'olani Neighborhood Zones.

Hotel: As with Residential apartments and condominiums, Hotel job multipliers are a function of amenity level, as well as things like average occupancy. As with assumed Hotel party sizes and occupancies, it was necessary first to assume an "Existing" multiplier – though there are no existing hotels in Kaka'ako – and use that as a basis for projecting future values. The assumed values were as follows (Table 2.19):

Table 2.19: Employment Multipliers Per Unit for Hotel Structures

Amenity Level	Existing*	Future	Source / Comments
Full-Service Visitor Hotel	0.80	0.66	Existing job multipliers based on interviews with hotel industry experts. Future values were again estimated at 82% of current values, reflecting typical declines in other multipliers listed above in Table 2.16.
Condo- Hotel	0.50	0.41	
Business Hotel	0.70	0.59	

* Not directly used in this analysis, but indirectly used as basis for assumed future value.
Note: Estimated multipliers based on consultation with industry. Actual labor rates may vary as a result of hotel developer decisions. Timeshares (with much lower multipliers) are not permitted in either of the TOD Alternatives.

2.3.5 Final Kaka'ako-Specific Operational Employment Calculation Procedures

The procedures were the same for all scenarios and all parts of Kaka'ako, and were carried out first at the building level:

1. Allocate specific jobcount figures for HECO, JABSOM, and Kewalo Bay to appropriate blocks.

2. For building uses with multipliers based on square feet, multiply the number of square feet by the appropriate multipliers from Table 2.16.

3. For Residential and Hotel structures, multiply the number of units by the appropriate multipliers from Table 2.17 and Table 2.19.

4. In all scenarios – Existing, Future Baseline, and both TOD Alternatives (A and B) – sum the various results by type of use to get total jobcounts for each block. Sum the block jobcounts to get Neighborhood Zone totals. Sum the Neighborhood Zone totals to get Kaka'ako-wide totals. Subtract Future Baseline from each TOD Alternative's numbers to get respective "impacts" by area or Kaka'ako-wide.

2.4 Estimated Kaka'ako-Specific Construction Employment – Methods and Assumptions

For Construction employment (results in Chapter 6), only the Future Baseline Condition and the two TOD Alternatives were analyzed. Existing structures or infrastructure are already in place and will generate no new construction.

"Construction jobs" for this analysis primarily relate to development of new structures (e.g., residential apartments or stores), but secondarily also to any needed new infrastructure (e.g., wastewater) or new public facilities in the area if and as needed (e.g., a new police sub-station).

As will be seen, the methodology for estimating construction jobs flows from estimated costs. Cost inputs for public facilities and infrastructure derive from sources and procedures described in more detail in the following Section 2.5 (and, for infrastructure, in Chapter 7). The procedure for estimating costs and then jobs for structures was more complex. Therefore, the present discussion focuses primarily on construction of new structures, albeit with presentation of multipliers for infrastructure and public facilities as well.

2.4.1 Types of Construction Jobs Studied

For new structures, the categories of analysis are similar to those used before, with some differentiation for Residential and Hotel:

- Residential (by type – low-rise, mid-rise, and high-rise)
- Hotel (by type – full-service leisure, business, condo-hotel)
- Civic/Public
- Office
- Retail
- Industrial
- Garage Parking

While only combined job figures from all these uses will be reported, these include two basic components:

1. Jobs related to "hard costs" – i.e., spending for actual on-site construction; and

2. Jobs related to "soft costs" – i.e., spending for architectural and design services, permitting, local finance activity, etc. These could be in or outside of Kaka'ako.

As with operational jobs, the numbers here represent direct jobs only.

2.4.2 General Approach to Kaka'ako-Specific Construction Employment Analysis

Meaning of Job Numbers: The standard approach to measuring construction employment is in terms of "job-years," not individual workers. The methods described

below generate jobcounts inclusive of both full- and part-time jobs for individual years, so that summing counts over years might or might not include the same construction jobs (and workers filling them) from one year to the next.

Calculation Procedures: The Hawai'i State Input-Output (I-O) 2007 Inter-County Model was used to estimate construction-related employment, based on:

- Construction dollars spent in the Hawai'i economy, broken down by …
- Particular broad economic sectors.

As detailed shortly, overall construction dollars for each new structure were estimated based on assumed dollars per SF for that type of structure, times square footage for each new structure as determined through methods and sources previously described in Section 2.1. This yielded a total construction cost for each new building.

The I-O model assumes that $1 million spent in one sector (e.g., food processing) produces a different level of economic activity, including different job-year counts, than $1 million spent in another sector (e.g., telecommunications). The relevant I-O economic sectors for this analysis were:

1. "Construction of Other Buildings" (i.e., "other" than single-family homes) – applicable for hard costs for all structures.
2. "Heavy and Civil Engineering Construction" – applicable for hard costs for needed new infrastructure.
3. "Architectural and Engineering (A&E) Services" – which represent the bulk of assumed soft costs.

The I-O Inter-County Model works differently for expenditures made in each county in Hawai'i. The O'ahu sector values were selected for this analysis, as Kaka'ako is part of the City and County of Honolulu.

As will be noted later in Section 2.6, I-O results from the Inter-County Model technically yield *statewide* results for "total" impacts, including multiplier or "ripple effects." But the parts of the Model used for this Kaka'ako-specific analysis focus on "direct" jobs only. These would likely be located entirely on O'ahu – most of them at Kaka'ako jobsites but some at construction headquarters or A&E offices elsewhere on the island.

Timeframe and Labor Productivity Issues: It is not possible to predict exactly what structures will be developed in exactly which year or even which decade. Therefore, the analysis focuses simply on *cumulative job-years for the build-out of each future scenario* (Future Baseline Condition and both TOD Alternatives).

This is based on the somewhat artificial conceit that there will be a point in time – for purposes of this EIS designated as the year 2035 – at which all new structures and any needed infrastructure will be complete and frozen in place for a period of time. In reality, of course, some structures may never be built, and others may be erected and then demolished and redeveloped before others are even begun.

Again, the nature of this analysis reflects a particular HCDA vision and assumes it will be realized in a certain way … and the associated numbers are properly interpreted as order-of-magnitude estimates rather than precise predictions.

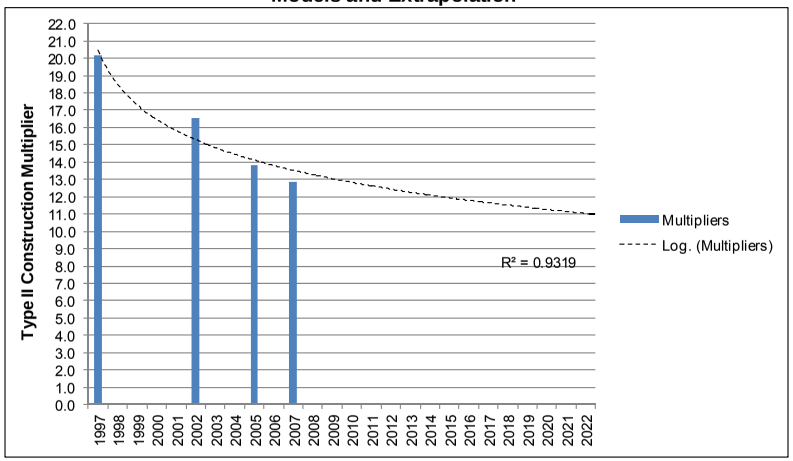
The lack of a timetable raises an issue for use of I-O direct employment multipliers. The I-O model assumes that increasing labor productivity over time means the same expenditure in any sector will generate progressively fewer jobs as each year goes by – i.e., the multipliers are year-specific and grow lower with time.

Furthermore, the current I-O model provides the basis for calculating sector-specific employment multipliers only from the year 2007 through the year 2017. The current model discounts the multiplier by 5% each year (i.e., assumes 5% fewer jobs per $1 million in real expenditures as each year goes by) – a linear pattern that would eventually result in near-zero jobs.

The timeframe/productivity issues were addressed as follows:

1. An average construction date mid-way between 2010 and 2035 – i.e., sometime around mid-2022 – was assumed.
2. The current I-O model is based on Economic Census and other source data for 2007. Type II multipliers for previous I-O models (based on data for 1997,[13] 2002, and 2005) were plotted for each of the three sectors ("Type II" multipliers actually include indirect and induced jobs, not just the direct jobs being estimated here, but they are used to help determine appropriate direct job ratios, as discussed in the immediately following Section 2.4.3.)

   Though this approach provided only a small number of points for each sector, the patterns were *not* linear (see Figure 2.4 for the example of "Construction of Other Buildings," the most critical sector). Several different types of trend-lines were mapped and extrapolated for all three sectors. Logarithmic trend-lines and extrapolations provided the best common approach for all three sections. For the example in Figure 2.4, this yielded a mid-2022 value of 11.0.
3. Similar procedures were followed for Type II multipliers for the other two sectors used in the construction employment analysis, generating initial Type II multiplier



[13] The 1997 I-O Model was differently organized, and the 1997 Type II Multiplier shown in Figure 2.4 reflects an average of *State* Model multipliers for construction of multi-family buildings, commercial buildings, and hotels.

values of 12.0 for "Heavy and Civil Engineering Construction" and 11.0 for "Architectural and Engineering Services."

Fixed vs. Place-Specific Employment Multipliers: Two key types of multipliers are involved –

- I-O multipliers yielding jobs from construction dollar values were *fixed* for each sector across all parts of Kaka'ako – i.e., they do not vary by location.

Figure 2.4: Construction Job Multipliers ("Other Buildings") from Recent I-O Models and Extrapolation

- However, average construction cost per SF was assumed to be greater for new structures in Neighborhood Zones located closer to Ala Moana Blvd. and the ocean – i.e., Pauahi and Auahi, as well as the Makai and Aloha Tower Special District zones.

2.4.3 Construction Employment Multipliers with Fixed Values in This Analysis

The State's 2007 I-O Model specifies Type II job multipliers by year, but *direct* job ratios (yielding immediate employment without "ripple effects" through the economy) must be calculated for the year 2007 and then discounted for future years by the same proportions that Type II multipliers are discounted. The final direct job ratios for the mid-2022 average construction year timeframe are shown for each of the three relevant sectors in the final column of Table 2.20:

Table 2.20: Calculation of Direct Job Multipliers, Construction Employment

	Type II Job Multipliers		Discount	Direct Job Ratios	
	2007	Mid-2022	(2022/2007)	2007	Mid-2022*
Construction of Other Buildings	12.9	11.0	85.5%	4.20	**3.59**
Heavy and Civil Engineering Construction	18.3	12.0	65.5%	9.40	**6.16**
Architectural and Engineering Services	14.5	11.0	76.1%	6.38	**4.85**

* The Mid-2022 Direct Job Multiplier equals 2007 multiplier times discount factor from Type II multipliers.
Source: Hawaii State 2007 Inter-County I-O Model, http://dbedt.hawaii.gov/economic/reports_studies/

Another value held constant in analysis was the percentage of total construction spending assumed to be for "soft costs" (represented by the Architectural and Engineering sector). Based on input from Kaka'ako landowners and reviews of other materials, this was set as 6%.

2.4.4 Construction Multipliers Assumed to Be Place-Specific in Kaka'ako

The total ("all-in") assumed average construction cost-per-SF values used in this analysis are shown in the following Table 2.21. Note that these are based on *current* costs. Construction costs vary over time, and are likely to escalate in the near future due to factors such as materials such as probable rising labor costs and increased demand for steel or other materials from expanding economies in Asia. However, it is difficult to predict what market adjustments will occur because of these factors, and so current figures are maintained for purposes of this analysis.

Figures in Table 2.21 apply to costs associated with new structures. These represent the great majority of potential new construction activity. For infrastructure and public facility costs, estimates were based on direct total numbers as described in following sections.

Table 2.21: Assumed Construction Costs Per SF, by Neighborhood Zone

	Pauahi, Auahi, ATSD, Makai	Rest of Kaka'ako	Source / Comments
High-Rise Residential	$480	$300	Based on input from various Kaka'ako landowners, general Honolulu contractors, and standard construction cost estimation handbook (RS Means Building Constuction Cost Data Book 2013, Honolulu Averages)
Mid-Rise Residential	$400	$250	
Low-Rise Residential	$340	$210	
Civic Buildings	$300	$250	
Office Space	$450	$250	
Retail Space	$300	$175	
Industrial Space	$125	$125	
Garage Parking Space	$250	$125	
Condo-Hotel	$400	N/A	
Business Hotel	$350	N/A	
Full-Service Visitor Hotel	N/A	$400	

2.4.5 Final Kaka'ako-Specific Construction Employment Calculation Procedures

The procedures were primarily carried out at the building level, as follows –

1. Determine which structures in the Future Baseline Condition or TOD Alternatives (A or B) were carried over from the Existing dataset, and exclude these from analysis. There were relatively few such buildings – about 9.3% of all "Existing" dataset buildings[14] were projected by HCDA's original spreadsheets, VIA, or HCDA 2013 updates to survive in Future Baseline dataset, and about 8.3% also survived in each of the TOD Alternatives (A or B) prepared for this analysis.

2. For each of the three future scenarios, calculate total all-in construction costs for each new building or development complex by multiplying total SF times construction costs shown in Table 2.21.

3. For each future scenario, assign 6% of the total construction value to "soft costs" and the remainder to "hard costs."

4. For each future scenario, multiply the "hard cost" total dollar amount by the direct job multiplier for "Other Buildings" – and the "soft cost" total dollar amount by the direct job multiplier for "Architects and Engineers" – shown in Table 2.20. Add the resulting two worker-year figures to get Total Job-Years. These figures are related to private structures assumed to be developed within Kaka'ako Neighborhood Zones.

5. For each future scenario, repeat steps #3 and #4 with the estimated total dollar value for any assumed required new public facilities or infrastructure (but for infrastructure, using the "Heavy and Civil Engineering" direct job multiplier from Table 2.20). These figures generally cannot be assigned to any one known Neighborhood Zone, and are thus separately shown as "Unallocated" in tables of results.

6. In all future scenarios – Future Baseline, and both TOD Alternatives (A and B) – sum the various building results to get total jobcounts (job-years) for each block. Sum the block jobcounts to get Neighborhood Zone totals. Sum the jobcounts for public facilities and infrastructure to get total "Unallocated" numbers. Sum the Neighborhood Zone and Unallocated totals to get Kaka'ako-wide totals. Subtract Future Baseline Condition numbers from numbers for each TOD Alternative to get respective "impact" by area or Kaka'ako-wide.

2.5 Estimated Effects on Kaka'ako Public Services and Facilities

Analysis of public services and facilities (Chapter 7) was conducted at two levels:

[14] The total number of Kaka'ako buildings in the final "Existing" dataset used for this analysis – the original HCDA dataset with Makai additions and other small modifications described in Section 2.1.1 – was 481, primarily located in the Mauka portion of Kaka'ako.

- Kaka'ako-specific; and
- Islandwide.

2.5.1 Overview of Methodological Approach

In general, information was gathered through one or both of two overall methods:

1. Direct inquiries to relevant State or County agencies;

2. Analysis of recent published documents to determine per capita operational costs and/or service availability.

The first method was given priority – if an agency was able to supply cost estimates, those estimates were accepted and used in the analysis. JMK Associates developed its own estimates and reports these in Chapter 7 only if the appropriate agency was unable to provide estimates.

The "public service" topics and relevant agencies are as follows (Table 2.22):

Table 2.22: Public Service Categories and Relevant Agencies

Topic	Relevant Agencies
Public Safety	City Fire Department City Police Department
Public Health	City Emergency Services Department Hospital availability (primarily private)
Education	State Dept. of Education
Parks and Recreation	City Dept. of Parks and Recreation HCDA

Public service and facility impacts involve both (a) assessment of adequacy of service for the public; and also (b) cost impacts for the agency. The two are of course inter-related, but the communication process yielded somewhat more frequent and specific information about cost impacts, as not all agencies have fixed standards about "adequacy" of service or facility levels. Information about service adequacy at the Kaka'ako-specific level is often incorporated in sub-sections labeled "Other Impacts" in the various parts of Section 7.2.

Particularly for public agencies, two separate types of cost "impacts" are of concern:

- **Operational Requirements and Costs** – primarily required additional personnel (but may also include supplies, equipment, etc.) required to maintain standards of service;

- **Capital Costs** – this refers to construction costs of required new *facilities* (e.g., schools), but also of public *infrastructure* (e.g., roads, water) needed for each

scenario. These costs were derived from past HCDA studies, supplemented by information from other project team consultants, as described further in Chapter 7.

Finally, an important overall principle for this analysis is that ***costs for islandwide impacts are independent of, and generally smaller than, Kaka'ako-specific impacts.*** This reflects the explanation previously given in Chapter 1, Section 1.6 about Kaka'ako-specific impacts being mostly due to shifts in population or economic activity expected to occur anyway, but islandwide impacts being due only to elements of the TOD Alternatives that would generate economic activity presumed not to occur otherwise (primarily construction of the three new hotels).

The islandwide public service/facility/infrastructure cost impacts are thus attributable only to this limited new economic activity and associated population. While Kaka'ako-specific costs may be estimated by agencies, the presumption for this analysis is that identical or highly similar costs would still be required on an islandwide basis for the population or economic activity "shifted" into Kaka'ako by the TOD Alternatives A or B.

For example, Honolulu Police Department personnel needs are estimated in Chapter 7 using the formula of 8.9 officers per 10,000 de facto population. As used in the Kaka'ako-specific analysis, this formula results in an estimate of additional police personnel costs that would be needed *in Kaka'ako* under TOD Alternative A or B – but might mostly still be required somewhere else on the island under the Future Baseline Condition. However, as used in the islandwide analysis, the formula yields the net islandwide additional police personnel needs associated only with the limited new economic activity generated by the TOD Alternatives.

Two important notes are associated with this principle of different and smaller islandwide costs than Kaka'ako-specific costs:

1. This is in no way an attempt to say that HCDA or Kaka'ako landowners/developers are immune from various agency growth impact fees just because "growth would happen anyway." Government operational and capital costs are required to pay for growth wherever it occurs, and HCDA has committed to working with agencies such as the State Dept. of Education (DOE) that have established such fees.

2. It should be acknowledged that some agency cost impacts could be slightly different if the additional Kaka'ako population growth permitted under TOD Alternatives A or B happened "somewhere else on the island." For example, DOE's impact fees differ depending on whether new housing units are multi-family units located in urban Honolulu or single-family units located in the Leeward suburbs. The problem is that it is impossible to say where the additional Kaka'ako population permitted under TOD Alternatives A or B would choose to live under the Future Baseline Condition, and so location-specific multipliers cannot always be applied. Given that TOD Alternatives A or B would result in more people living in Honolulu multi-family units, it seems reasonable to assume many would otherwise still be living in other Honolulu multi-family units with identical DOE multipliers.

2.5.2 Further Methodological Details

Methods were ultimately *agency-specific*, and these methods are described in various parts of Chapter 7. That is, each public agency had its own way of estimating impacts and cost implications. For example, the State DOE used certain fixed assumptions about school enrollment impacts for projected new developments, while other agencies responded to the inquiries on a much more judgmental basis – i.e., they did not indicate whether their assumptions about costs or other impacts were based on fixed multipliers or simply on their in-house experience and expertise.

Thus, while JMK Associates sent the same basic project descriptions and projected population effects to each agency, we did not prescribe nor request a standardized basis for agency use of this information to determine impacts. We simply reported agency responses.

In some cases, because of the complexity of the analytic framework (e.g., difference between "Kaka'ako-specific" and "islandwide" impacts), there was initial agency confusion about what was intended, and a series of communications was needed to clarify what was needed for this assessment. If and as needed, JMK Associates generated its own tentative assessments based on things such as recent budgets divided by population, and sent these to agencies for approval or revision. But unless otherwise stated in Chapter 7, no results are presented here that did not have at least tentative agency approval following these oral and written communications.

Because of the agency-specific nature of the analyses, there is a potential for conceptual inconsistency among the various analyses. For example, some analyses stress uncertainties in Kaka'ako-specific impacts related to the fact that service areas may extend past Kaka'ako itself into other portions of urban Honolulu, and it is unknown how much population might grow in the overall area under the Future Baseline – while other analyses do not touch on this issue. These differences reflect the nature of different agency-specific communications.

Finally, it should be noted that ***all agency communications took place in 2013 and actually focused only on the Future Baseline and what is now labeled "TOD Alternative A,"***[15] as TOD Alternative B was not developed until 2014. However, as will be shown in the various following chapters focusing on analysis results, it was readily apparent that Alternative A was the more intensive or "worst-case scenario" in comparison to TOD Alternative B. Furthermore, the TOD Alternative B results for things like residential units, population, and operational jobs were still fairly close to the Alternative A – with estimated levels more than 90% of those for Alternative B.

[15] The numbers shared with public agencies in late 2013 were revised slightly *downwards* in subsequent analyses. That means agency estimates of needs can be considered conservative, relative to the final numbers in this study.

Therefore:

1. If an agency said in 2013 that impacts from TOD Alternative A would require some new facility (without providing any computations or formulas), it was reasonably but conservatively assumed that the same facility at the same cost would still be required for the lower-density TOD Alternative B.

2. If the agency provided formulas or concurred with computations proposed by JMK Associates in 2013, those formulas/computations were simply run again in 2014 with new inputs (generally population or residential units) for TOD Alternative B.

As noted above, the complexity of this project required lengthy communications and generated some initial agency confusion in 2013, and so the 2014 approach – which built on the 2013 results – seemed an appropriate and conservative method.

2.6 Estimated Statewide/Islandwide Construction-Related Impacts – Methods and Assumptions

Results are in first part of Chapter 8. As earlier discussed (Sections 1.6.2 and 1.6.3, and again above in Section 2.5.1), islandwide impacts are actually smaller than Kaka'ako-specific ones because they are limited only to those elements that are assumed not to occur *anywhere on the island* unless a TOD Alternative (A or B) is implemented.

For construction-related impacts, these are essentially limited to (a) development of three hotels; and (b) any increment in construction of public facilities or infrastructure resulting from islandwide (not Kaka'ako-specific) population growth. A small additional source of economic impacts associated with the construction phase – initial purchases by part-time residents – is described below in Section 2.6.2. The same section provides further detail on how "islandwide" impacts are usually virtually identical with "statewide" impacts."

While smaller in magnitude than Kaka'ako-specific impacts, islandwide economic impacts have more elements (i.e., there are other types of impacts besides employment) and yet the methodology is simpler in that the inputs are primarily limited to hotel and potential additional public facility/infrastructure construction costs.

2.6.1 Types of Islandwide Construction-Related Economic Impacts Studied

The analytic procedure generates four types of economic impacts:

1. Output, or level of economic activity, measured in dollars;

2. Household earnings associated with this activity;

3. Employment (along with population supported by these jobs); and

4. Total State tax revenues and General Excise Tax (GET) returned to City and County of Honolulu for rapid transit purposes (although these are actually used for the later government fiscal cost-revenue analysis).

Each of these is presented at two different levels:

a. *Direct impacts* flowing from the initial round of expenditures (for employment, direct impacts would be identical to the Kaka'ako-specific results generated through methods and assumptions discussed previously in Section 2.4); and

b. *Total impacts*, including economic multiplier effects as dollars "ripple" through the economy. These total impacts sum the effects of two different types of expenditure "ripples:"

   - Indirect effects, when businesses buy from other businesses; and
   - Induced effects, when employees spend their wages and salaries.

   The calculated total impacts are statewide, although they would be overwhelmingly located on O'ahu, as explained below.

2.6.2 General Approach to Islandwide Construction Impact Assessment

Kaka'ako-specific impacts were determined by summing various results for the Future Baseline Condition and both TOD Alternatives (A and B), and subtracting to determine "impact." But islandwide impact calculations can *begin* with changes in key inputs (expenditures) and apply multipliers to determine impacts such as employment – a more succinct approach that generates the same end results.

Primary Analysis: The approach used here is a standard application of the Hawai'i Input-Output (I-O) Model developed by the Hawai'i State Dept. of Business, Economic Development, and Tourism (DBEDT) to measure the relationships among different sectors of the Hawai'i economy.

Specifically, the 2007 Hawai'i Inter-County I-O Model was used, as this allows calculation of effects from expenditures made on the island of O'ahu in particular.[16] The 2007 I-O Model is the most recent available version.

The I-O model provides "Type II" multipliers for estimating the total effects, and also includes ratios (e.g., earnings to output, or jobs to output) which are in effect the direct multipliers. These multipliers are all applied to the initial round of Kaka'ako-specific construction spending (conceptually the same as "direct output") calculated for:

[16] http://dbedt.hawaii.gov/economic/reports_studies/2007-inter-county-io/.

- Hotels, by procedures previously described in Section 2.4;

- Public facilities and infrastructure (due to islandwide economic/population growth only), by procedures described in Section 2.5.

For employment impacts, the construction timing and labor productivity issues previously addressed in Section 2.4.2 on Kaka'ako-specific impacts were addressed exactly as described in that section, by using the estimated mid-2022 direct and total job multipliers calculated there. Also see discussions in Section 2.4.1 on hard and soft costs, and Section 2.4.2 on "job-year" concept.

The Inter-County I-O Model Type II multipliers actually generate *statewide* rather than O'ahu-specific *islandwide* results. Since the preliminary analysis was drafted in 2013, DBEDT has made available County I-O Models, including one for the City and County of Honolulu. JMK Associates has elected still to keep presenting statewide results only – and to consider them as practically synonymous with "islandwide" results – for several reasons:

1. The statewide results are more complete, and provide proper and appropriate inputs to the fiscal cost-revenue analysis for State government expenses.

2. The Honolulu County I-O Model Type II multipliers are so close to the statewide multipliers that it is always accurate to say the vast or overwhelming majority of total impacts would occur on O'ahu. Below (Table 2.23) are examples for the I-O Model sectors used for the primary Construction phase impact analysis, as explained further in immediately following text:

Table 2.23: Inter-County Versus County Multipliers for Construction Analysis

	Sector: "Construction of Other Buildings"			Sector: "Heavy and Civil Engineering Construction"			Sector: "Architectural and Engineering Services"		
	Honolulu County	Inter-County (Statewide)	County as % of State	Honolulu County	Inter-County (Statewide)	County as % of State	Honolulu County	Inter-County (Statewide)	County as % of State
Output	2.00	2.13	**93.7%**	2.04	2.15	**95.2%**	1.95	2.03	**95.9%**
Employment*	12.08	12.87	**93.9%**	17.53	18.32	**95.6%**	13.72	14.46	**94.9%**
Earnings	0.58	0.63	**92.5%**	0.62	0.64	**95.9%**	0.86	0.88	**97.3%**
State Taxes	0.13	0.14	**96.8%**	0.08	0.08	**94.7%**	0.13	0.14	**97.0%**

* 2007 value -- these multipliers vary by year, but 2007 is the base value

Thus, the combined total O'ahu results from these three sectors would be about 95% of the statewide value; employment and earnings also about 95%; and State taxes about 96%.

Secondary Analysis: A little-studied additional economic impact comes from part-time residents' initial expenditures on interior decoration and finishing, and in some cases large purchases such as on-island automobiles. This is properly considered as part of the "Construction" phase because, unlike ongoing operational impacts such as normal daily expenditures by part-time residents when on island, they are mostly a one-time

large expenditure that occurs before or about the same time as initial occupancy. Construction hard cost estimates typically exclude such expenditures.

In truth, there are no solid economic studies on this phenomenon, although assumptions here are partly based on discussions with a limited number of O'ahu Realtors. Results from this analysis should be considered very tentative, but are included because (a) they provide some recognition of this economic phenomenon; and (b) due to conservative assumptions (including no consideration of later spending for the same purposes when the units are resold to new purchasers), we are confident that these are underestimates of actual economic benefits.

2.6.3 Specific Multipliers and Related Assumptions

Four sets of multipliers – from four I-O economic sectors – were employed, as follows:

Table 2.24: Multipliers for Hard Costs (Hotels or Public Facilities)

Sector: "Construction of Other Buildings"	Direct	Total
Output	1.000	2.132
Employment*	3.588	11.000
Earnings	0.297	0.628
State Taxes**	0.069	0.136

* Adjusted for mid-2022
** Used in later fiscal cost-revenue analysis

Table 2.25: Multipliers for Soft Costs (All Construction)

Sector: "Architectural and Engineering Services"	Direct	Total
Output	1.000	2.033
Employment*	4.854	11.000
Earnings	0.595	0.884
State Taxes**	0.082	0.139

* Adjusted for mid-2022
** Used in later fiscal cost-revenue analysis

Table 2.26: Multipliers for Hard Costs (Infrastructure)

Sector: "Heavy and Civil Engineering Construction"	Direct	Total
Output	1.000	2.146
Employment*	6.157	12.000
Earnings	0.297	0.643
State Taxes**	0.016	0.083

* Adjusted for mid-2022
** Used in later fiscal cost-revenue analysis

Table 2.27: Multipliers for Initial Purchases of Part-Time Residents

Sector: "Retail"	Direct	Total
Output	1.000	1.827
Employment*	11.975	17.300
Earnings	0.363	0.584
State Taxes**	0.079	0.125

* Adjusted for mid-2022
** Used in later fiscal cost-revenue analysis

These multipliers[17] were applied to appropriate estimated direct output (i.e., estimated initial expenditures), except for Retail multipliers for initial purchases of part-time residents (Table 2.27). Retail multipliers were applied to the estimated total expenditure figures for this economic activity, which were calculated as follows (Table 2.28), based on previously calculated estimates of differences between the Future Baseline

[17] Technically, the "Direct" figures are *ratios*, and the Total figures are *multipliers*.

Condition and the two TOD Alternatives (A and B) for various levels of Residential condominium properties:

Table 2.28: Key Assumptions for Calculating Part-Time Resident Initial Expenditures

Type of Assumption	High Amenity	Mid Amenity	Low Amenity
Interior Finishing (Furnishings, Art, Home Entertainment, etc.)*			
Assumed Expenditure per SF	$25.00	$15.00	$5.00
Assumed Percent Spent on O'ahu	70%	80%	90%
Automobile Purchases**			
Assumed Average Value of Car Purchase	$30,000	$17,500	$5,000
Assumed Percent Purchasing Cars on O'ahu	50%	65%	80%

* Applied to change (from Future Baseline to each TOD Overlay Scenario) in square footage held by part-time residents, minus existing SF occupied by part-time residents

** Applied to change in units held by part-time residents, minus existing units occupied by part-time residents

Source: JMK Associates, based on discussions with O'ahu Realtors active in Kaka'ako

Amenity levels reflect the same building-specific projected proportions of part-time residents as set forth in preceding Section 2.3.4 and Section 2.2.5 before it. It should be noted that Realtors generally reported that more affluent purchasers spent more overall but also imported proportionately more from off-island.

Finally, population supported by total employment requires (1) assumed percentages of construction workers temporarily imported from off-island, and (2) an assumed number of dependents per Hawai'i worker. The proportion of non-Hawai'i construction workers can vary greatly over time depending on the level of construction activity, and no definitive estimate of an overall average is available. However, a conservative *average* 20% is assumed, reflecting Act 168, Hawai'i Session Laws of 2010, which requires contractors for certain State construction projects to employ at least 80% Hawai'i residents. The ratio of dependents per on-island worker is determined by using Census data to divide total O'ahu population (excluding estimated population in households by the total number of workers, a process yielding a population-to-worker ratio of 1.976.[18]

2.6.4 Final Islandwide Construction Impact Calculation Procedures

The procedures for this analysis were carried out at the level of *change* from the Future Baseline Condition to TOD Alternatives for each element (e.g., change in part-time residential economic activity, or each hotel building), as follows –

1. For each building or other element, begin with the previously determined incremental construction value, allocated to hard costs and soft costs. This provides the initial direct output value.

[18] Data source was U.S. Census American Community Survey 2011 three-year figures centering on 2010. There were 63,055 households with zero workers, and a conservatively small estimated household size of 1.0 for such household meant subtraction of 75,666 from the total population (954,140) before dividing by 44,552 workers to determine the 1.976 value.

For the initial part-time residential expenditures, direct output is estimated by multiplying the assumptions in Table 2.28 by the appropriate increment in *new* square footage or units held by part-time residents.[19]

2. Apply the various I-O multipliers shown in Table 2.24 through Table 2.27 to determine results for direct and total output, direct and total earnings, and direct and total employment. (Results for total State taxes are also calculated, but held for use in the subsequent government cost-revenue analysis.)

3. Resulting job numbers are multiplied by 20% to estimate numbers of out-of-state workers, and the remaining Hawai'i worker numbers are multiplied by 1.976 to determine local population supported by employment.

2.6.5 Interpretation of Results

It is important to note that results yield islandwide employment and economic activity created *or maintained* by project construction activity. Construction employment is episodic. During sustained construction downturns, the indirect and induced islandwide effects of construction may wither, affecting storekeepers or others not in the actual construction workforce. However, during more normal times, as construction workers move from one project to another, these indirect and induced effects are maintained as one project is completed and another begins.

It is also important to remember that the results reflect cumulative impacts of all construction over time between 2010 and the presumed build-out date of 2035. They would not occur at any one moment in time.

2.7 Estimated Islandwide Operations-Related Impacts – Methods and Assumptions

Islandwide operational impacts (second part of Chapter 8) reflect only (a) islandwide spending by hotel guests; and (b) incremental spending by additional part-time residents (increase from Future Baseline Condition to each TOD Alternative).

2.7.1 Types of Islandwide Operations-Related Economic Impacts Studied

These are exactly the same as for islandwide construction-related economic impacts: direct and total output, earnings, employment, and (for use in the subsequent government fiscal analysis) State taxes and GET returned to the City and County of Honolulu. (See foregoing Section 2.6.1.)

[19] As this step required identification and deduction of existing part-time residential SF or units, it was the only step in the islandwide analysis that required a further search of the modified HCDA datasets, in order to determine *new* part-time residential activity only.

The key difference between islandwide operational impacts and construction impacts is that operational impacts are presented in terms of *average annual effects* after a theoretical full build-out, while construction impacts are cumulative over time.

2.7.2 General Approach to Islandwide Operational Impact Assessment

As with islandwide construction impacts, islandwide operational impacts were calculated by applying I-O multipliers to an initial direct output (i.e., expenditure) figure. Such direct spending by hotel guests and by additional part-time residents is estimated in the following Table 2.29 by use of historical visitor expenditure data gathered by DBEDT or, in recent years, by the Hawai'i Tourism Authority (HTA). O'ahu-only expenditure data for visitors staying in hotels only or in condominiums only were weighted (by visitor-days per year) to produce average values in 2012 dollars for the three-year period from 2010 to 2012, and then increased by a standard 20% factor to reflect the likelihood that visitors in these properties would be somewhat higher-than-average spenders (as land values for urban Honolulu sites would almost certainly result in higher-than-average room rates).

The average daily figures in Table 2.29, particularly the total figures (with a slight adjustment for inter-island airfare), were then multiplied by 365.25 to generate annual expenditure figures, which provide the necessary annual direct output figures to be used with I-O multipliers.

2.7.3 Specific Multipliers and Related Assumptions

The I-O Model provides a set of "Visitor Expenditure" (VE) Type II multipliers appropriate for cumulative hotel guest spending, and a set of "Personal Consumption Expenditure" (PCE) Type II multipliers appropriate for residential spending, and the latter was used for part-time residents as well. The Type II multipliers are used for total effects. The sort of sector-specific information used to calculate direct construction multipliers in Section 2.6.2 and Section 2.6.3 are not provided directly in the model but may be calculated by a matrix-algebraic procedure that JMK Associates carried out after discussions with and direction from DBEDT economists.

Along with total State taxes, GET returned to the County is also calculated here for input to the later government fiscal cost-revenue analysis. The County portion is 0.5% of output *except* for the portion of direct output consisting of expenditures for lodging. That rate is 0.459%, for reasons explained subsequently in Section 2.8.4, Table 2.32 in conjunction with explanation of the effective room tax rate on O'ahu.

The same assumed population-to-worker ratio of 1.976 calculated previously (Section 2.6.3) on construction assumptions and methods) is again used to calculate annual population supported by total operational employment.

Table 2.29: Calculation of Estimated Daily Average Expenditure by Property Type

	Original Average Weighted 2010 - 2012 Expenditures		Adjusted Data Used for Analysis			
(in 2012 Dollars)	Hotel Only	Condo Only	Full-Service Hotel[1]	Business Hotel[1]	Condo-Hotel[2]	Part-Time Residents[2]
Total Lodging	**$95.84**	**$72.61**	**$115.00**	**$115.00**	**$87.13**	**$43.30** [3]

2.7.4 Final Islandwide Operational Impact Calculation Procedures

The procedures for this analysis were carried out at the level of *change* from the Future Baseline Condition to the TOD Alternatives for each element (e.g., change in part-time residential economic activity, or each hotel building), as follows –

1. For each type of hotel visitor or part-time resident, use the appropriate average daily visitor expenditure figure (minus 50% of inter-island airfare, as 50% assumed spent on O'ahu) multiplied by 365.25 to calculate direct output.

2. Apply the various I-O multipliers shown in Table 2.30 and Table 2.31 to determine results for direct and total output, direct and total earnings, and direct and total employment. (Results for total State taxes and County share of GET are also calculated, but held for use in the subsequent government cost-revenue analysis.)

3. Resulting job numbers are multiplied by 1.976 to determine local population supported by employment.

2.7.5 Interpretation of Results

Again, it is important to note that results yield islandwide employment and other economic activity created *or maintained* by project operational activity. If nothing else changes in the economy, the results would be additional jobs, population, etc. However, if some other part of the economy weakens, these impacts could replace the fading components and thus maintain existing jobs, earnings, etc.

Additionally, it is always important to remember that results reflect build-out *scenarios* rather than specific plans. Small differences in results due to small differences in scenario inputs should not be taken as particularly meaningful.

For example, the TOD Alternative A scenario has three hotels totaling 1,000 units. Alternative B as developed in 2014 also has three hotels, with a slightly higher total unit count of 1,044. (This is one of the few specific ways in which the TOD Alternative B scenario had slightly more rather than less density compared to Alternative A.) In terms of statewide/islandwide economic impacts, the small effects of these additional hotel units are largely but not entirely offset by TOD Alternative B having fewer units for, and numbers of, part-time residents than Alternative A. This means some of the statewide/islandwide operational economic impacts are very marginally higher for TOD Alternative B than for Alternative A – but for all practical purposes both the inputs and also the operational impacts are identical.

J·M·K John M. Knox & Associates, Inc. Oct. 15, 2014

2.8 Estimated Government Fiscal Impacts

2.8.1 General Approach to Fiscal Cost-Revenue Analysis

Government costs and revenues (those borne by taxpayers) are analyzed in Chapter 9 at two levels: (1) for the State; and (2) for the City and County of Honolulu. Both are appropriately analyzed on an islandwide basis. At each level, separate results are provided for:

- Construction phase (cumulative results for all construction);
- Operational phase (point-in-time annual figures).

This analysis is subject to a number of uncertainties and differences from typical fiscal cost-revenue analyses (which are usually applied to much more concrete and specific proposed projects) – see discussion in Section 9.2.

Although the results presented in Chapter 9 also include qualitative discussion about the general principles of cost-effectiveness of concentrated versus dispersed development, it cannot be clearly determined whether costs and revenues would differ significantly for the relatively small (on an islandwide scale) shifts of population or workers into or out of Kaka'ako for the Future Baseline Condition versus either TOD Alternative (A or B). Therefore, the fiscal cost-revenue analysis is based only on those same project elements mentioned in the two preceding sections dedicated to islandwide impacts – i.e., development of three hotels and associated visitor spending; incremental changes in part-time resident spending; and changes in islandwide governmental public facility/infrastructure costs.

As with islandwide construction and operational impacts just discussed, the analytic technique *begins* with foregoing "impacts" that feed into the final analysis – e.g., the difference in expenditures subject to taxation between the Future Baseline Condition and each TOD Alternative. Some of the final costs or revenues were already determined as by-products of preceding analyses, and some are calculated in this step by applying additional multipliers here to other impact numbers.

2.8.2 Types of Costs and Revenues Included in This Analysis

Construction Phase – Government Costs: For both State and County governments, costs are estimated as the sum of –

- Previously determined infrastructure and/or facility construction costs; and
- Service costs for construction workers imported from out-of-state.

Construction Phase – State Revenues: Total State tax revenues were already determined as a by-product of the "Islandwide Construction Impact" assessment. These

came from summing up the various construction component revenues from the I-O Model State Tax multipliers specified in foregoing Table 2.24 to Table 2.28.

Construction Phase – County Revenues: County revenues come from the portion of General Excise Tax (GET) on construction costs returned to the City and County of Honolulu for transit development and operations.

Operational Phase – Government Costs: For both State and County governments, operational costs are service costs for transient populations (i.e., hotel visitors and the increment in part-time residents from the Future Baseline Condition to each TOD Alternative), as well as possible additional operating costs to serve additional residential population supported.

Operational Phase – State Revenues: Total State tax revenues were already determined as a by-product of the "Islandwide Operational Impact" assessment. These came from summing up the various construction component revenues from the I-O Model State Tax multipliers specified in foregoing Table 2.30 and Table 2.31.

Operational Phase – County Revenues: County revenues are calculated as two alternative bottom lines. The first is the sum of –

- County share of GET from incremental expenditures of transient populations; and
- Property tax (building component only) for three hotels.

An additional possible source of County revenues is the City and County of Honolulu's share of the Transient Accommodations Tax (TAT) for the three hotels.[20] Until recently, 44.8% of all TAT revenues were divided among the four counties, with the City and County of Honolulu receiving 44.1% of that 44.8%. However, the Legislature has capped the total county share (at $93 million as of the 2013 Legislature's action signed into law as Act 161). This means that any additional TAT generated in the near term would yield no additional tax revenues for the City and County.

However, the hotels envisioned for Kaka'ako would not be developed in the short term, but sometime between now and, presumably, 2035. It is possible the cap will be maintained, perhaps at a higher level, indefinitely. However, this course of action may also change if and as expanding tourism places more demands on counties for services and new infrastructures. Therefore, purely for illustrative purposes, a second County Revenue bottom line is calculated that includes the TAT revenue that would be generated if the previous formula is reinstated.

2.8.3 Types of Costs and Revenues Excluded from This Analysis

Note should be made of two exclusions:

[20] Note that State TAT receipts would be included among all other State taxes bundled into the I-O Model's State Tax multipliers.

1. *Property tax revenues from assessed land value component* – As a conservative step, it is assumed that urban properties for hotel use are already zoned for some high-intensity use, such that this property tax component would be unchanged from the Future Baseline Condition to either TOD Alternative. (Property tax rates on land are currently an identical $12.40 per $1,000 assessed value for "Commercial," "Industrial," and "Hotel/Resort" categories.)

2. *Total State or County service costs or revenues associated with islandwide full-time resident population created or maintained by changes in employment* – Although it is an open question whether governments can always achieve the same total overall level of service as population grows, both State and County governments usually are able to achieve fairly balanced budgets. That is, revenues collected from the overall population tend all to be expended on that population.

   Thus, revenues and service costs roughly cancel out and may be excluded from the analysis. (These are different from service costs for transient populations, where there is not such an inherent equilibrium. Additionally, the resident population impacts are not necessarily new bodies on-island – they may be "maintained" rather than "created" – but visitors and part-time residents are assumed always to be new transient population.)

   However, as a conservative step in the analysis, we do include such increases in islandwide operating and facility construction costs as reported only by the key agencies specified in the foregoing Section 2.5 on Public Facilities and Services. This is done to guard against the possibility that it is too facile to assume an automatic equilibrium of full-time resident costs and revenues, and/or to serve as a marker for possible decreases in overall level of services as population increases.

2.8.4 Explanation of Specific Inputs and Multipliers Added for This Analysis

The following additional variables and values are added at this stage of analysis:

1. *Hotel Site Building Values* – Though property tax assessments ultimately reflect market values as determined by sales, initial assessed values are usually based on the value of construction, and so those values are used here.

2. *Property Tax Rates for Hotel Buildings* – As per current Honolulu rates for both land and buildings, a rate of $12.40 per $1,000 value is employed.

3. *O'ahu Share of GET* – 0.5%, applied to direct and total output (portions occurring on O'ahu – a calculation requiring use of DBEDT's County I-O Model), except for the portion applied to expenditures for lodging (see below).

4. *Effective O'ahu TAT and GET Rates for Accommodations Expenditures* – For the alternative illustrious analysis of County revenues from the TAT under the old system, the previously-mentioned percentages of 44.1% and 44.8% must be

multiplied by the TAT tax rate. While the current TAT is specified in law as 9.25%, that 9.25% applies to the pre-tax or "net" billing. The TAT portion of the final "gross" billing (i.e., including both GET and TAT) work out in practice to ***8.1167%.*** The product of these three percentages is 1.6036% of the total gross expenditures for accommodations (an expenditure figure previously generated during analysis of "Islandwide Operational Impacts").

Total GET is nominally 4.5%, of which 4.0% goes to the State and 0.5% (or 1/9 of 4.5%) to the City and County. However, because GET by State law is applied to the gross billing, hoteliers and other retailers typically attach a 4.716% figure to the pre-tax net billing. This leads to an effective GET rate returned to the City and County of ***0.4594%.*** Calculation of the foregoing 8.1167% and 0.4594% figures is explained in Table 2.32.

Table 2.32: Calculating Effective TAT and GET Rates for Lodging Bills

	Tax Rate Applied to Pre-Tax Net Billing	Dollar Amounts	Effective Tax Rate on Final Gross Bill
Example Pre-Tax Billing		$100.00	
TAT Added to Bill	9.2500%	$9.25	8.1167%
Total GET Added to Bill	4.7120%	$4.71	4.1347%
Final Gross Bill		$113.96	
O'ahu Share of GET (1/9)	*0.5236%*		*0.4594%*

Source: Computations by JMK Associates, following consultations with Hawai'i Hotel & Lodging Association

5. *State Per-Capita Service Costs for Transient Populations* – an estimated figure of $1,518.44 annually was generated by the following procedure:

   - Utilize operating costs for broad categories of the State budget available in the *Hawai'i State Data Book 2011* (Table 9.22) for the ten fiscal years from 2003 to 2012, in order to avoid depending on budget figures from any one year (as these may be affected by particular economic circumstances).
   - Determine budget categories for services required largely or entirely by residents only (e.g., Welfare payments), versus those required for both residents and transients.[21]
   - Convert to standard 2012 dollars using the Honolulu Consumer Price Index.
   - For each year, divide the sum of outlays for all services required by both visitors and residents by the sum of resident and average daily visitor population. Take the average for the ten-year period.

[21] State services assumed to be for transients as well as residents were: Public Safety, Highways, Conservation of Natural Resources, Health, Culture and Recreation, and Debt Service. On average, these have accounted for about 27% of State operating expenses each for FY 2003 to 2012.

6. *County Per-Capita Service Costs for Transient Populations* – an estimated figure of $945.19 annually was generated by the following and very similar procedure:

   - Utilize operating costs for broad categories of the City/County *Proposed Operating Program and Budget*[22] for the ten fiscal years from 2003 to 2012.
   - Determine budget categories for services required largely or entirely by residents only (e.g., Human Services), versus those required for both residents and transients.[23]
   - Convert to standard 2012 dollars using the Honolulu Consumer Price Index.
   - For each year, divide the sum of outlays for all services required by both visitors and residents by the sum of resident and average daily visitor population. Take the average for the ten-year period.

2.8.5 Final Calculation Procedures

Construction (Cumulative):

1. State Revenues taken from previous analysis of islandwide construction impacts.
2. Multiply State service cost of $1,406 times off-island construction job-years.
3. Add previously calculated islandwide State facility/infrastructure cost for final cost figure.
4. County revenues calculated as 0.5% GET times total output from previous analysis.
5. Multiply County service cost of $968.50 times off-island construction job-years.
6. Add previously calculated County facility/infrastructure cost for final cost figure.
7. Compare costs and revenues for each level of government.

Operations (Annual):

1. State Revenues taken from previous analysis of islandwide operational impacts.
2. Multiply State service cost of $1,406 times increments in visitors, part-time residents.
3. County revenues begin with 0.5% GET times total output from previous analysis.
4. Add hotel building costs times $12.40 rate for initial County revenue estimate.
5. For second County revenue total, also add TAT rate of 1.6036% times total accommodations expenditures from previous analysis.
6. Multiply County service cost of $968.50 times increments in visitors, part-time residents.
7. Compare costs and revenues for each level of government.

[22] Various documents available at http://www1.honolulu.gov/budget/execbgt/index1.htm.

[23] County services assumed to be for transients as well as residents were: Public Safety, Highways and Streets, Sanitation, Culture-Recreation, and Debt Service. On average, these have accounted for about 59% of State operating expenses each for FY 2003 to 2012. The relatively greater burden imposed by transient populations on the City and County was a factor in the decision to show County revenues from the TAT under the old system, as tourism pressures on counties will presumably motivate continued political efforts to remove or alter the current cap on TAT revenues shared with counties.

3. RESULTS: KAKA'AKO-SPECIFIC LAND USE AREAS AND UNITS

The results reported in this chapter – residential units, visitor units (TOD Alternatives only), and square footage for various land uses – are initial figures used by other consultants and by JMK Associates for our own subsequent population and employment impact assessments.

3.1 Methods and Caveats

The typical presentation style for EIS economic analysis is to provide tables that show at least some of the calculations, with various assumptions and multipliers referenced in footnotes. Because of the complexity of the datasets used for Kaka'ako-specific results in this Chapter 3 through Chapter 6, that is not possible.

This is why methods used to determine the following results were described in detail in the foregoing Chapter 2 – and for these particular results, Section 2.1 of that chapter. In that Section 2.1, Figure 2.2 provides the block numbering system referenced in output tables here.

Results depend on the assumption that the underlying inputs from the HCDA Synoptic Survey output, along with inputs from VIA and HCDA, comprise a fairly accurate inventory of Existing structures and uses in Kaka'ako – and also that the Future Baseline Condition and the two TOD Alternative (A and B) datasets from the same sources provide reasonable illustrative scenarios for the future under the current and proposed new Rules.

3.2 Results – Existing Scenario

These "Existing" results ultimately do not generally affect the impact assessment – which is based on a comparison of Future Baseline Condition each respective TOD Alternative (A and B) results – but they do provide a baseline for understanding levels of development anticipated under each future scenario.

Table 3.1 provides Kaka'ako-wide results, as well as breakdowns by general area (Mauka, Makai, Aloha Tower Special District Site) and specific Neighborhood Zones for the Mauka area. As per discussion in Section 2.2.5, the number of residential units in the Existing dataset (8,618 units, derived primarily from the HCDA Synoptic Survey output) is considerably higher than that reported by the U.S. Census.

ATSD N.Z.	-	-	-	-	-	-	-	77,600	-	-	-	-

* JABSOM is the John A. Burns School of Medicine (University of Hawai'i), and the Community Center (Children's Discovery Center) – kept as distinct uses for purposes of traffic analysis based on this output. In some later analyses, they are collapsed into the "Civic" category.

Columns for Hotel Units and SF are inserted to maintain comparability with the later Table 3.3 and Table 3.4, which include this information for TOD Alternatives B and A, respectively.

3.3 Results – Future Baseline Condition

Table 3.2 provides overall results for the Future Baseline Condition. Comparison to the "Existing" figures in the foregoing Table 3.1 indicates the level of development for likely build-out of Kaka'ako under current Rules – substantial increases in Residential (square footage at 235%, more than tripling, though larger unit sizes resulting in 145% increase in unit count) and Retail (more than doubling at 115%), and significant increase as well in Office (about 67%) and Industrial (about 23%), though with a modest decline in Civic space (about -15%).

Parking is anticipated to involve a consolidation into Garage Parking, leaving very little Surface Parking.

Under the Future Baseline Condition, about half the total square footage listed in Table 3.2 would, if built out, be located in the Pauahi (28%) and Auahi (21%) Neighborhood Zones – where the dominant landowners of Howard Hughes and Kamehameha Schools have master-planned their holdings. More than half the potential total Residential units would be in the same two areas (29% Pauahi and 27% Auahi).

3.4 Results – TOD Alternatives

Table 3.3 provides overall results for TOD Alternative B, and Table 3.4 provides the same for the higher-density Alternative A. Both involve even more Residential development than the Future Baseline Condition, but less for most other uses, as detailed further in the following discussion of "Impacts."

The geographical *proportionate* distribution (i.e., percentage of totals) would change only slightly from build-out under the Future Baseline Condition, mostly by increasing the Pauahi Neighborhood Zone percentages a bit. For TOD Alternative B, the numbers in Table 3.3 indicate that, 30% of total square footage would be in Pauahi and 19% in Auahi – for Residential units, 32% and 22%, respectively. For TOD Alternative B, the numbers in Table 3.4 work out to 31% of total square footage in Pauahi and 21% in Auahi – for Residential units, 32% and 24%, respectively.

3.5 Results – Impacts

Impacts are defined as the difference between the respective TOD Alternative figures and the Future Baseline figures (i.e., TOD Alternative B minus Future Baseline and TOD Alternative A minus Future Baseline). Table 3.5 and Table 3.6 provide these results.

On a Kaka'ako-wide basis, the TOD Alternatives would generate these impacts:

- At build-out, ***substantial increases in Residential square footage and units*** (for Alternative B, 26% more units and 32% more square footage than under the Future Baseline – and for Alternative A, 37% and 44% more). There would also be increases over the Future Baseline for Garage Parking space (9% for Alternative B, 13% for Alternative A), and for Civic (about 8% for each). And of course there would be limited new Hotel development under each of the TOD Alternatives.

- However, the TOD Alternatives both result in ***reduction in Office, Retail, and Industrial space*** compared to build-out for the Future Baseline Condition. The Office and Industrial reductions are roughly -20% and -4% for each TOD Alternative. The build-out scenario generated for Alternative B resulted in a somewhat greater drop in eventual Retail square footage for Alternative B (-13%) than for Alternative A (-6%).

  Note that these negative percentages involve comparison to the Future Baseline figures, not to the Existing figures. Development of all these land uses is still foreseen as significant additions to the current inventory of Office, Retail, and Industrial activities, just not to the same extent as under the Future Baseline Condition.

- Particularly in regard to Residential increases for the higher-density TOD Alternative A, the Neighborhood Zones with the greatest changes in absolute numbers of additional total units would be, starting with the most heavily affected: Pauahi, Thomas Square District, Auahi, Kapi'olani, and Central Kaka'ako.

  The order is similar for the lower-density TOD Alternative B scenario, except that the Auahi Neighborhood Zone in this scenario would have much less (but still some) additional Residential-unit development.

- Unaffected by either TOD Alternative would be the limited Residential development projected under the Future Baseline Condition for the Civic Center Neighborhood Zone, the Sheridan Neighborhood Zone, and still zero Residential development for all of Makai (exclusive of the Aloha Tower Site, which is seen as shifting to a Residential and additional Retail emphasis).

4. RESULTS: KAKA'AKO-SPECIFIC POPULATION

This chapter reports on results for several types of Kaka'ako-specific[24] populations –

- Full-time residential population; and
- "De facto" population – the number of residents or visitors actually present on an average day[25] – which has three components:
  - Full-time residents actually present (excluding people temporarily away);
  - Average part-time resident population;
  - Average visitor population in three presumed hotels.

4.1 Methods and Caveats

Methods used to determine the following results are described in detail in the foregoing Section 2.2. It should be understood that the Future Baseline and TOD Alternative (A or B) population figures are order-of-magnitude estimates for a full build-out under each scenario, whether that actually occurs in the year 2035 or sometime thereafter. Actual population will vary according to specific developer plans, and these numbers should be viewed as approximate maximal numbers.

4.2 Results – Existing Scenario

As with estimated land use and unit counts (Chapter 3), these "Existing" results ultimately do not affect the impact assessment – which is based on a comparison of Future Baseline and TOD Alternative results – but provide a baseline for understanding levels of development anticipated under each of the three future scenarios.

Table 4.1 provides Kaka'ako-wide results, as well as breakdowns by general area (Mauka, Makai, Aloha Tower Special District Site) and specific Neighborhoods for the Mauka area. As was discussed in Section 2.2.5, the HCDA Synoptic Survey output) is considerably higher than that reported by the U.S. Census. Therefore, Table 4.1's estimated "existing" full-time resident population of 13,549 – based primarily on the HCDA unit counts – is also higher than the 2010 Census figure (10,673).

[24] As noted in Chapter 1, Section 1.6, islandwide population impacts are conceptually different, and are addressed in the following Chapter 8.
[25] A different interpretation of "de facto population" might include workers and retail/restaurant customers present at any particular point in time. Estimating customer counts exceeds the scope of this study. The following Chapter 5 looks at total jobcounts, but not necessarily the number present at particular points in time. Caution should be taken in simply adding population and jobcount numbers, due to factors such as employee absences and the possibility that some Kaka'ako workers are also Kaka'ako residents.

Table 4.1: Estimated Population – Existing Scenario

	Total Full-Time Residential Population	Total De Facto Population	*De Facto Resident Population*	*De Facto Part-Time Resident Population*	*De Facto Visitor Population*
KAKA'AKO TOTAL	**13,549**	**13,824**	***12,804***	***1,020***	**-**
By General Area					
Mauka	13,326	13,613	*12,593*	*1,020*	-
Makai	223	211	*211*	-	-
ATSD (Aloha Tower Special District)	-	-	-	-	-
By Neighborhood Zone					
Pauahi N.Z.	1,912	1,865	*1,807*	*58*	-
Auahi N.Z.	3,796	4,364	*3,587*	*777*	-
Central Kaka'ako N.Z.	1,522	1,464	*1,438*	*25*	-
Civic Center N.Z.	209	197	*197*	*0*	-
Kapi'olani N.Z.	4,206	4,112	*3,975*	*137*	-
Sheridan N.Z.	863	819	*816*	*3*	-
Thomas Sq. Dist. N.Z.	818	793	*773*	*20*	-
Makai N.Z.	223	211	*211*	-	-
ATSD N.Z.	-	-	-	-	-

Notes: The Makai population, taken from the 2010 Census, consists solely of the non-residential Kewalo Basin population, who may have been transients or passenger/crew of cruising vessels temporarily in port. However, this number is assumed to hold constant in all scenarios. This was the only population number taken directly from the U.S. Census, though the Census data were used to estimate things such as average household size for various building types and places within Kaka'ako, which were then applied to unit numbers in Table 3.1 in order to estimate the population figures above.

The Aloha Tower Special District site currently consists of a HECO power generation facility (now on standby basis) with no residential population of any type.

A column for "De Facto Visitor Population" (hotel guests) is inserted to maintain comparability with the later Table 4.3 and Table 4.4, which include this information for TOD Alternatives B and A, respectively.

J·M·K John M. Knox & Associates, Inc. Oct. 15, 2014

4.3 Results – Future Baseline Condition

Table 4.2 shows population results for the Future Baseline Condition. Comparison to the comparable "Existing" figures in the foregoing Table 4.1 indicates both full-time and de facto populations would more than double (to about 33,500 for full-time, a bit more for de facto), consistent with the increased number of units estimated in Section 3.3. This projected population increase flows directly from increase in units under current Rules.

Consistent with the geographical distribution of Residential units (Section 3.3), the numbers in Table 4.2 indicate that theoretical full-time population for build-out of the Future Baseline Condition would be primarily concentrated in the Pauahi Neighborhood Zone (31%), as well as the Auahi (22%) and Kapi'olani (21%) zones.

4.4 Results – TOD Alternatives

Consistent with the increased Residential space discussed previously in Section 3.4, ***both TOD Alternatives result in more population at build-out than under the Future Baseline Condition.***

Overall results are in Table 4.3 (TOD Alternative B) and Table 4.4 (Alternative A). For Alternative B, full-time residential and overall de facto populations are estimated at about 42,500 and 44,500 respectively. The higher-density Alternative A, the build-out numbers increase to about 46,200 and 48,200 respectively.

An average daily visitor population of roughly 1,700 people in each scenario would be spread among three assumed hotels (and thus represents just a small part of the estimated overall de facto populations).

Compared to the percentages for the Future Baseline Condition noted above, the *proportionate* geographical distribution of full-time residential population would again change only slightly, with a few more percentage points in the Pauahi Neighborhood Zone (about 34% for each TOD Alternative) and a few less in the Auahi (18% for TOD Alternative B and 20% for Alternative B) and Kapi'olani (20% for Alternative B and 19% for Alternative A) zones.

Table 4.2: Estimated Population – Future Baseline Condition

	Total Full-Time Residential Population	Total De Facto Population	*De Facto Resident Population*	*De Facto Part-Time Resident Population*	*De Facto Visitor Population*

Sheridan N.Z.	824	783	*778*	*4*	-
Thomas Sq. Dist. N.Z.	3,416	3,301	*3,228*	*73*	-
Makai N.Z.	223	211	*211*	-	-
ATSD N.Z.	-	-	-	-	-

Notes: All indicated population is associated with residential housing structures, except for the assumed continuation of Kewalo Basin non-residential population in the Makai area.

No "De Facto Visitor Population" is shown because no short-term transient accommodations (e.g., hotels) are permitted in Kaka'ako under the present Rules.

The Aloha Tower Special District site is assumed under this scenario to be developed as a retail and office complex, with no residential component.

Thomas Sq. Dist. N.Z.	5,734	6,378	*5,419*	*124*	*835*
Makai N.Z.	223	211	*211*	-	-
ATSD N.Z.	268	772	*254*	*50*	*469*

Notes: All indicated population is associated with residential housing or transient accommodation structures, except for the assumed continuation of Kewalo Basin non-residential population in the Makai area.

The Aloha Tower Special District site is assumed under this scenario (and under TOD Alternative B) to be even more intensively developed as a retail and office complex, but this time with a substantial residential component.

4.5 Results – Impacts

Impacts are again defined as the difference between the respective TOD Alternative figures and the Future Baseline figures (i.e., TOD Alternative B minus Future Baseline and TOD Alternative A minus Future Baseline). Table 4.5 and Table 4.6 provide these results.

- At build-out under the TOD Alternative B scenario, the full-time residential and total de facto populations would be respectively 27% and 31% greater than under the Future Baseline Condition (based on current Rules). Under the higher-density Alternative A, they would be 38% and 43%, respectively, greater than under the Future Baseline.

  Again, the population increase primarily reflects the estimated increase in total units shown in Table 3.5 and Table 3.6 of Chapter 3. The estimated population increase percentages are slightly greater than the unit increase percentages (26% for Alternative B and 37% for Alternative A) because of growth in places or building types with slightly higher average household sizes or other parameters (such as vacancy rates). However, these differences in percentage points are quite small.

- Percentage increases in full-time residential population impacts are estimated to outstrip percentage increases in part-time population impact. This is because additional development capacity assumed for both TOD Alternatives (A and B) would occur in many parts of Kaka'ako, whereas substantial numbers of part-time residents are attracted only to certain parts of the area, such as those with ocean views.

- However, the addition of visitor population (hotel guests) under both TOD Alternatives means the combined de facto population impact – including hotel guests, part-time residents, and full-time residents actually present on any given day – is slightly larger than the full-time resident population impact for each of the TOD Alternatives (both A and B).

Table 4.5: Population – TOD Alternative B Impacts

5. RESULTS: KAKA'AKO-SPECIFIC OPERATIONAL EMPLOYMENT IMPACTS

This chapter is concerned with "operational employment" – i.e., full- and part-time jobcounts associated with the *operation* of public and private economic activities, as opposed to the *construction* of new buildings or infrastructure. (Construction employment is addressed in the following chapter, and includes public facility and infrastructure projects based in part on these operational jobcount estimates, as per later discussion in Chapter 7.)

The tables in this chapter contain results for estimated total jobcounts in Kaka'ako under all scenarios – Existing, Future Baseline, and both TOD Alternatives – derived by first estimating jobcounts for each specific types of land/building use, and then summing.

5.1 Methods and Caveats

Methods used to determine the following results are described in detail in the foregoing Section 2.3. All the cautions described in the past few chapters apply here as well –

- Reliance on inputs from the initial HCDA datasets, as well as VIA and HCDA update assumptions previously described.
- Reminder that the following figures are not precise projections, but rather order-of-magnitude estimates for a full build-out under each scenario, whether that actually occurs in the year 2035 or sometime thereafter.

The first caveat is particularly important here due to the large number of Office jobs that flow from the assumed large amount of Office space in Kaka'ako. As discussed in Chapter 1, Section 1.2, there are serious questions about whether that much Office development will truly materialize in Kaka'ako by the assumed 2035 build-out time – but the analysis is actually one of build-out of the HCDA vision whenever it really occurs.

Finally, "total jobcount" should not be interpreted as a point-in-time estimate of workers actually present in Kaka'ako. Employees work different shifts (day/night, weekday/ weekend), and factors such as vacations and illnesses affect the actual number of workers present at any one time.

5.2 Results – Existing Scenario

"Existing" results provide context for the subsequent impact assessment that involves comparing the two different future scenarios. The following Table 5.1 indicates a Year 2010 total Kaka'ako jobcount of approximately 31,600 – the vast majority located in the Mauka area, and more than 60% due to Office activity.

Table 5.1: Estimated Kaka'ako-Specific Operational Jobcount – Existing Scenario

	TOTAL	Residential Bldg. Jobs	Hotel Jobs	Civic Jobs	Office Jobs	Retail Jobs	Industrial Jobs	JABSOM Jobs	Surface Parking Jobs	Garage Parking Jobs
KAKA'AKO TOTAL	**31,546**	**509**	**-**	**4,920**	**19,558**	**3,603**	**2,351**	**440**	**57**	**107**

Makai	**2,660**	-	-	116	1,584	277	232	440	-	11
Aloha Tower Special District (ATSD)	**40**	-	-	-	-	-	40		-	-
By Neighborhood Zone										
Pauahi N.Z.	**8,406**	52	-	127	6,487	1,013	693	-	23	11
Auahi N.Z.	**3,397**	300	-	-	1,626	1,423	6	-	15	27
Central Kaka'ako N.Z.	**5,348**	28	-	605	3,342	235	1,124	-	5	10
Civic Center N.Z.	**2,331**	5	-	1,125	1,148	29	11	-	2	12
Kapi'olani N.Z.	**5,758**	100	-	136	4,967	470	51	-	12	22
Sheridan N.Z.	**350**	11	-	185	140	13	-	-	0	1
Thomas Sq. District N.Z.	**3,255**	14	-	2,626	264	144	194	-	-	14
Makai N.Z.	**2,660**	-	-	116	1,584	277	232	440	-	11
ATSD N.Z.	**40**	-	-	-	-	-	40	-	-	-

Notes: For purposes of this analysis, the "Community Center" (Children's Discovery Center) has been combined with "Civic" in this and subsequent tables.

A column for "Hotel Jobs" is inserted to maintain comparability with the later Table 5.3 and Table 5.4, which include this information for the two TOD Alternatives (A and B).

5.3 Results – Future Baseline Condition

Under the Future Baseline Condition (i.e., under current Rules), Table 5.2 contains estimates that sum to a Kaka'ako-wide total jobcount of about 51,200 full- and part-time jobs – about a 62% increase over the estimated Existing total in Table 5.1.

Note, however, that the vast majority of this employment growth is in the Office category (reflecting assumed growth in Office space), which would comprise about 73% of the operational jobs under this scenario.

Under this Future Baseline Condition, most jobs still remain in the Mauka area, but Makai jobs increase as a proportion of the total, though again primarily due to assumed development of substantial Office space.

At the level of Neighborhood Zones, the distribution of jobs at build-out in Table 5.2 is relatively more even across areas than was the distribution of population for the Future Baseline Condition (discussed previously in Section 4.3). However, the Pauahi Neighborhood Zone still would have the single largest share (25%), followed by the Thomas Square District zone (18%). Numbers in the table equate to 12% to 14% for each of these Neighborhood Zones: Auahi, Central Kaka'ako, Kapi'olani, and Makai (exclusive of the Aloha Tower Special District, or ATSD). Jobs in all these Neighborhood Zones, however, are dominated by the "Office" category, which has in reality been a very slow-growing category.

Table 5.2: Estimated Kaka'ako-Specific Operational Jobcount – Future Baseline Condition

ATSD N.Z.	**336**	-	-	-	136	197	-	-	-	3

5.4 Results – TOD Alternatives

Consistent with the decreased Office, Retail, and Industrial space discussed previously in Section 3.4, ***both TOD Alternatives result in fewer jobs at build-out than under the Future Baseline Condition.*** That is, the fundamental nature of either one of the TOD Alternatives, A or B is a relative switch in emphasis from commercial activity to residential development.

The theoretical ultimate total jobcount remains a little higher for TOD Alternative A (about 45,160 in Table 5.4) than for Alternative B (about 43,650 in Table 5.3). Office jobs also drop from the Future Baseline Condition level for TOD Alternative A, and even more for Alternative B, but still comprise more than two-thirds of the total jobcount under each scenario.

The projected reduction (compared to the Future Baseline) in jobs is all in the Mauka area, as the Makai jobcounts – exclusive of the ATSD – in both Table 5.3 and Table 5.4 are identical to the Future Baseline jobcount number in Table 5.2 (7,180). However, the number of jobs associated with the ATSD site is larger for each TOD Alternative (about 1,650) than under the Future Baseline Condition, reflecting assumed additional development capacity there.[26]

The *proportionate* geographic distribution of jobs, compared to the Future Baseline Condition percentages discussed above, shows more change than did population distribution (Section 5.4) – mostly a sharp reduction in potential future jobs in the Thomas Square District Neighborhood Zone (down to 8% in both TOD Alternatives) due to Office jobs declining more than anywhere else. However, as with population, the Pauahi zone gains some percentage points (up to 26% for Alternative B and 28% for Alternative A), as does the Auahi zone (up to 15% for each TOD Alternative). The Makai and ATSD zones also increase a few points proportionately. The reality of these shifts once more depends not only on landowner action to implement these changes, but also on a substantial increase in market demand for Office space.

[26] The ATSD parcel is the site of the current HECO power plant facility. It should be noted that HECO has taken the power plant offline but currently plans to retain it for back-up purposes – *not* to redevelop it as assumed for the Future Baseline and TOD Overlay scenarios. Again, this study looks at what HCDA envisions and/or would permit under current or proposed Rules; it does not obligate landowners to implement the scenarios described here.

5.5 Results – Impacts

Table 5.5 and Table 5.6 again show "impacts" as the difference between results for each of the TOD Alternatives and results for the Future Baseline Condition results. These reflect the basic overall nature of the difference between either of the TOD Alternatives versus the Future Baseline Condition – i.e., substantially more residential development, somewhat less commercial activity – flowing from the land/building use changes documented in Chapter 3:

- About 12% fewer total Kaka'ako-wide jobs (about 6,050 in absolute number) under TOD Alternative A than under the Future Baseline Condition – and 15% fewer (about 7,560) under Alternative B – with total job reductions greatest in the Thomas Square District and Central Kaka'ako Neighborhood Zones. The density reductions in Alternative B would also result in the loss of more potential jobs in the Pauahi zone.

- A particularly large proportionate reduction (more or less 20% for each TOD Alternative) in Office jobs, accompanied by a proportionately large (33% for TOD Alternative A and 19% for Alternative B) increase in Residential management/ maintenance jobs – though the *absolute* number of projected additional Residential jobs is still relatively low (about 300 for Alternative A and under 200 for Alternative B).

Note: Figures in parentheses are negatives.

6. RESULTS: KAKA'AKO-SPECIFIC CONSTRUCTION EMPLOYMENT IMPACTS

This chapter provides estimates of the *cumulative* Kaka'ako-specific construction-related employment impacts, in terms of "job-years." Results are provided for Future Baseline Condition and the two TOD Alternatives only, as construction has already occurred for "Existing" Kaka'ako structures.

The construction impacts come primarily from development of new buildings – determined by comparing the HCDA Future Baseline dataset (as well as the TOD Alternative datasets that represent adjusted versions of the Future Baseline dataset) to the Existing dataset in order to identify new structures. However, some of the construction activity also comes from development of (a) additional public facilities identified in the following Chapter 7, and (b) additional public infrastructure as identified by project consultants Belt Collins Hawai'i and Nelson\Nygaard (also Chapter 7).

6.1 Methods and Caveats

Construction Related to New Structures: Methods used to determine following results in this chapter are described in detail in the foregoing Section 2.4. All the cautions described in the past few chapters apply here as well. For these construction results, it should be remembered that (a) numbers represent the sum of construction effects assumed to take place over time, but no specific timetable is assumed; and (b) the results describe the cumulative effect of theoretical *full build-outs* for each scenario. The datasets used for the analysis imply the great majority of Kaka'ako structures would be new under these full build-out scenarios (Table 6.1). Whether such full build-outs could occur by 2035 is beyond the scope of this analysis.

Table 6.1: Percentage New Development (in SF) for Both Future Scenarios

	Residen-tial SF	Hotel SF	Civic SF	Office SF	Retail SF	Indus-trial SF	Parking Garage SF
Future Baseline	74.1%	N/A	26.1%	80.1%	87.0%	90.2%	79.2%
TOD Alternative B	80.9%	100.0%	27.5%	75.5%	85.5%	89.8%	81.1%
TOD Alternative A	82.5%	100.0%	27.5%	76.3%	86.6%	89.9%	81.9%

Source: JMK Associates analysis of datasets described in Section 2.1.1.

As one conservative counter-weight to the inherently non-conservative assumption of full build-out, only construction impacts are estimated – implicit demolition is ignored. Also omitted (and difficult to estimate) is infrastructure provided by private landowners.

Construction Related to New Public Facilities and Infrastructure: Except for provision of multipliers, these methods were entirely set forth in the earlier Section 2.4 and/or Section 2.5 (explaining methods for following Chapter 7, which provides facility and infrastructure cost estimates needed to generate construction job figures).

J·M·K John M. Knox & Associates, Inc. Oct. 15, 2014

6.2 Results – Future Baseline Condition

Exclusive of whatever jobs may be generated by Makai public infrastructure, Table 6.2 indicates a total of about 55,840 job-years of construction for full build-out of the Future Baseline Condition, more than half associated with residential buildings.

Under the Future Baseline Condition, about 38% of the total construction job-years over time would be located in the Pauahi Neighborhood Zone, 23% in Auahi, and 11% in the Thomas Square District Neighborhood Zone.

6.3 Results – Results – TOD Alternatives

Table 6.3 and Table 6.4 show indicates significantly more estimated job-years of construction for the TOD Alternatives (about 69,200 for Alternative B and 76,200 for the higher-density Alternative A) than under the Future Baseline Condition.

As with the Future Baseline Condition, but to an even greater extent, construction activity and employment is concentrated:

- In development of Residential structures and Parking; and
- Primarily although not completely within the Pauahi (about 40% for both TOD Alternatives) and Auahi (19% for Alternative B and 23% for Alternative A) Neighborhood Zones – i.e., proportionately a little more in Pauahi and, for Alternative B, a little less in Auahi than the Future Baseline Condition figures above. The percentage for the Thomas Square District zone remains the same at 11% for each TOD Alternative.

Some of the "Unallocated" infrastructure and public facility direct construction jobs could also be located outside Kaka'ako – e.g., construction of schools or other public facilities serving Kaka'ako but not located in Kaka'ako. Consistent with text discussion, however, public infrastructure jobs related to Makai development (outside the ATSD) are not counted, and so "Unallocated" jobs are most likely to be in the Mauka or ATSD areas.

6.4 Results – Impacts

Table 6.5 and Table 6.6 shows "impacts," defined as the difference between results for each of the TOD Alternatives and results for the Future Baseline Condition results. As with operational jobs, results for construction jobs reflect the basic overall nature of the difference in the Future Baseline versus the two TOD Alternatives – substantially more residential development, somewhat less commercial activity – flowing from the land/building use changes documented in Chapter 3:

- Overall, about 37% more construction job-years would be required to build out the TOD Alternative A scenario than the Future Baseline Condition, and 24% more than the Future Baseline for Alternative B.
- Most of the additional construction employment is associated with residential development (61% increase over Future Baseline number for TOD Alternative A, 42% for Alternative B), though with a proportionately high increase in construction job-years associated with needed new public facilities and infrastructure as well.
- For both TOD Alternatives, there are small decreases in construction employment associated with Office, Retail, and Industrial development, though these are roughly balanced by additional construction employment associated with additional Parking Garage and Hotel development.
- Again, impacts are numerically most apparent in the Pauahi and Auahi Neighborhood Zones.

Some of the "Unallocated" infrastructure and public facility direct construction jobs could also be located outside Kaka'ako – e.g., construction of schools or other public facilities serving Kaka'ako but not located in Kaka'ako.

7. RESULTS: PUBLIC SERVICES AND FACILITIES

This chapter presents results for Public Safety (fire and police), Public Health (emergency services and hospitals), Education, and Parks and Recreation. At issue are both social aspects (adequacy of public service) and cost impacts borne by public agencies and taxpayers. Cost impacts proved relatively easier to quantify. All impacts are discussed by specific agency/category.

Agency-specific results are presented in separate sections *both* at the Kaka'ako-specific *and* the islandwide levels, with islandwide cost results for public facilities and infrastructure feeding into construction job results for the following Chapter 8. The Kaka'ako-specific results also informed the foregoing Chapter 6 results on Kaka'ako-specific direct construction employment.

Also feeding into both Chapter 6 and subsequent chapters are construction parameters and costs for public infrastructure projects – e.g., wastewater systems – gathered by other EIS consultants and/or carried over from past HCDA studies.

Within each level of analysis (Kaka'ako-specific and islandwide), two categories of impact are considered:

- Annual ongoing operational impacts and associated costs (e.g., additional personnel required to serve an expanding population) for public services and facilities;
- Any one-time construction needs and associated costs for facilities (e.g., need to build a new structure that would otherwise not have been required) and for public infrastructure.

7.1 Methods and Caveats

Public Services and Facilities: Most methods used to determine the following results are described in detail in the foregoing Section 2.5, which addressed both the Kaka'ako-specific and islandwide methodologies. As explained there, Kaka'ako-specific impacts are not included with islandwide impacts because they reflect assumptions about *where* people will live on O'ahu, not *whether* they will be on O'ahu at all. Islandwide cost impacts flow only from net islandwide impacts calculated in the following Chapter 8.

It is also worth reiterating that methods here are agency-specific – that is, each agency responded to available information about likely population effects with its own internal procedures and calculations, sometimes derived as part of a communication process back and forth with JMK Associates. Therefore, some additional methodological information unique to particular agencies is provided in this chapter.

Finally, it is further worth reiterating that original agency responses in 2013 involved only the Future Baseline Condition and what is now labeled TOD Alternative A. Stated impacts for TOD Alternative B derive from one of two approaches:

1. If the agency provided formulas or ways of computing needs based on inputs such as population or residential units, those formulas were applied to appropriate TOD Alternative B inputs.
2. If the agency simply said the level of development projected for Alternative A would require X new facilities and Y new personnel, at estimated total cost Z, the same values X, Y, and Z were conservatively assumed to apply to the lower-density TOD Alternative B scenario as well.

All the cautions described in the past few chapters again apply here as well, and it should again be particularly remembered that the impacts are for a theoretical *full build-out* of Kaka'ako under the various scenarios. Few or none of the projected full needs are imminent, although the current spate of actual and proposed residential construction projects in Kaka'ako is catching the attention of public agencies and generating discussions with HCDA about ways to address developing impacts on public services.

Public Infrastructure: Cost information was processed but not generated by JMK Associates. Some relevant multipliers were provided in the foregoing Section 2.5. All other sources, assumptions, and methods are discussed in the following Section 7.2.7.

7.2 Kaka'ako-Specific Impacts

As has been the case for results in the past several chapters, this section looks at what will happen in Kaka'ako alone under each TOD Alternative (A and B), regardless of whether net islandwide effects would be the same under the Future Baseline Condition. Information for each agency is followed by summary tables for each TOD Alternative, A and B, at the end of the section (Table 7.15 and Table 7.16, Section 0).

7.2.1 Public Safety – Fire Department

According to the Honolulu Fire Dept. (HFD),[27] consequences include the following:

Present Conditions – Kaka'ako is currently served by the Kaka'ako Fire Station (located in the western or 'Ewa portion of Kaka'ako at 555 Queen St.) and the Pāwa'a Fire Station (located at 1610 Makaloa St, .just past the eastern or Diamond Head district boundary of the Kaka'ako Community Development District). Both stations were built more than 40 years ago, and would eventually require replacement due to age alone.

[27] Letter of Sept. 20, 2013 from HFD Chief Manuel P. Neves and various follow-up discussions with Battalion Chief Socrates Bratakos of the Fire Prevention Bureau.

Operational Impacts – The projected Kaka'ako residential population growth under the Future Baseline Condition would, at full build-out, require an increase of ten on-duty fire-fighters (FFs) (or 30 FFs to cover all shifts), two support staff, and two fire trucks. Twice those numbers (i.e., 60 FFs, four support staff, etc.) would need to be added for TOD Alternative A, with the same needs conservatively assumed for the somewhat lower-density TOD Alternative B.

Thus, the Kaka'ako-specific impact of either TOD Alternative (A or B) would be annual operating costs associated with the difference in these numbers – which amount to 30 FFs, two support staff, and two fire trucks.

With a current average HFD staff salary a little under $82,000, the average annual personnel cost for each TOD Alternative (A and B) would be about $2.6 million (for the additional 32 positions). One-time purchase costs for fire trucks would be about $500,000 each, or $1 million total.

Facility Construction Impacts – While the current fire stations will need to be replaced even if there is zero population growth in their service areas, expanded future Kaka'ako populations (and attendant needs for more FFs and equipment) under the various scenarios would necessitate larger and thus more costly replacement structures.

HFD estimates the additional construction cost for each station – over and above replacement costs for stations of the current size – would be in the range of $8 to $10 million. One expanded station would be needed to house the additional FFs and fire trucks under the Future Baseline Condition, and a second expanded station would be needed under each of the TOD Alternatives. Thus, the one-time facility cost impact of the TOD Alternatives (either A or B) would be the $8 to $10 million construction increment for a second station, which will be conservatively operationalized as a single higher-end $9.5 million for purposes of subsequent fiscal cost-revenue analysis. (Including fire trucks, one-time costs are $10.5 million.)

Other Impacts – Fire Chief Neves wrote that HFD "ability to provide services in Kaka'ako will also be impacted by transit-oriented development, including rail infrastructure, traffic calming, and pedestrian friendly street features, and the potential increase in vertical height of the area's buildings." HFD was, however, unable to quantify such impacts. Regarding slower response times for fires at the top of tall buildings, these would depend on various building-specific factors – such as availability to firefighters of various numbers of elevator banks or stairwells, presence of an auxiliary water supply above 400 feet, layout of floors, and other parameters. (Note that difficulties associated with the provision of water above 400 feet would be associated only with TOD Alternative A and not TOD Alternative B.)

7.2.2 Public Safety – Police Department

Present Conditions: The Honolulu Police Dept. (HPD) currently has no police facility in Kaka'ako, though the island's Main Station on South Beretania St. is just above Kaka'ako's mauka boundary (S. King St.). Kaka'ako is part of HPD's District 1, Central Honolulu, which includes the downtown Honolulu area from Liliha Street to Punahou Street and from Round Top Drive to Ala Moana Beach Park, including the Aloha Tower.

Operational Impacts: According to the HPD,[28] the projected Kaka'ako residential population growth under the Future Baseline Condition would, at full build-out, require an increase of about 30 police officers, based on the December 2012 ratio of 8.9 police officers per 10,000 people in District 1. There would also be additional costs at the main station – e.g., equipment, supplies, vehicles, etc., though some of these would of course also be required if the projected population increase occurred elsewhere in District 1 or other places supported by the main station. While the salary range for a City and County police officer currently is between $4,439 to $6,392 per month, HPD concurred with an *augmented* average salary estimate from JMK Associates of $8,000 per month ($96,000 annually) in order to include appropriate portions of the supplemental costs. Using the projected Future Baseline Condition total de facto population of 33,844 (Table 4.2), this results in an estimated average annual operating cost impact of $2.89 million at full build-out under that scenario.

Under TOD Alternative B, the ratio of 8.9 police officers applied to the de facto population at full build-out would generate a total demand for nearly 40 police officers – and, at $96,000/year for salaries and support, a total operating cost increase of $3.8 million. The impact, or difference in figures between the two scenarios, would thus be about 9.45 more police officers and $907,500 additional personnel costs per year.

Under the higher-density TOD Alternative A, this same ratio would generate a total demand for 43 police officers – and, a total operating cost increase of $4.12 million. The impact, or difference in figures between the two scenarios, would thus be nearly 13 more police officers and $1.23 million additional operating costs per year.

Additionally, under the TOD Alternative A, the HPD would need to rent space for a small field and report writing office in which officers can complete reports, miscellaneous office-type duties, and other tasks. Discussions between JMK Associates and HPD officials generated an assumed rental cost of $30,000/year ($2,500/month). The same figure may conservatively be applied to TOD Alternative B.

Facility Construction Impacts: HPD envisioned no construction of new police facilities for TOD Alternative A. Therefore, none are envisioned in this analysis for the lower-density Alternative B either.

[28] Letter of Sept. 13, from Asst. Chief Clayton G. Kau (for Chief Louis M. Kealoha), and various follow-up communications with Research Analyst Emily Ogasawara.

Other Impacts: Although the HART rail stations in or near Kaka'ako would be constructed with or without the proposed TOD Alternatives, HPD wished to emphasize its estimate that the overall transit project, regardless of population implications, would require an additional 251 employees of various kinds, with annual cost of about $17.3 million.

7.2.3 Public Health – Emergency Services

Present Conditions: The City and County of Honolulu Emergency Services Dept.[29] has two divisions –

- Ocean Safety and Lifeguard Services Division. This Division is City-funded and focuses on marine emergencies. It is not directly affected by population or economic changes in Kaka'ako (except indirectly through harbor and beach park usage) or any other specific geographical neighborhood on land. However, the Department is in discussions with HCDA to provide land on a lease basis for a new Ocean Safety Facility at Kewalo Basin, to replace a current facility in the Waikīkī Natatorium, which is to be demolished. The Department expects to request City Council funding approval in FY2016. This activity is independent of the proposed Kaka'ako TOD Alternatives, and so no further discussion of Ocean Safety functions will be made here.

- Emergency Medical Services Division (EMSD). This Division – administered by the City but ultimately funded by the State Dept. of Health – provides emergency medical service and ambulance transportation in response to land-based crises. The EMSD will be the primary focus of this discussion.

  Islandwide, there are 20 EMS units and two single-response units. These are EMS emergency response vehicles staffed with a single paramedic and treats victims on scene until a transport unit arrives. Of these, five EMS units serve the overall metropolitan area from Waikīkī to Kalihi/Iwilei. There are no specific service-area boundaries, but Kaka'ako is usually served by either (1) the Makiki and Metro One EMS units at 1426 Young St., or (2) the Baker One unit located at the Queen's Medical Center, 1301 Punchbowl St.

  Given current population growth, the EMSD considers metropolitan Honolulu to be on the cusp of needing a new EMS unit. The Department has also been (as of late 2013) in discussions with HCDA about another 24-hour/day site in Kaka'ako (in the area where Fisherman's Wharf now stands) to meet this need. A tentative plan is to locate a trailer from which the ambulance crew could operate, as has been done in other parts of the island. Although this action, if it occurs, would also be independent of substantial future Kaka'ako population growth, it does raise the strong possibility that Kaka'ako would be effectively served long before 2035 by at least one new EMS station – although that station may also serve other nearby neighborhoods as well.

[29] Information in this section reflects various communications with and from Director Mark Rigg, October to December 2013.

Operational Impacts: The question for analysis here is what additional future needs, if any, the EMSD would face if the present Kaka'ako de facto population and jobcount were to grow by 2035 to the levels estimated in Chapters 4 and 5.

Future EMSD needs would of course depend on overall islandwide and metropolitan growth, as there is no official separate Kaka'ako EMSD service area. However, the EMSD estimates that growth under the Future Baseline Condition would contribute to need for a second new EMS station. Based on the new station currently proposed for Kaka'ako, it would have annual operating costs of about $1.04 million (primarily for salaries). However, no additional service would thereafter be required for TOD Alternative A – or, logically, for the lower-density TOD Alternative B. Therefore, the impact as defined for this EIS would be $0, according to the agency.

Facility Construction Impacts: Full build-out costs for the proposed new Kaka'ako EMS unit would be about $4 million, which provides the best estimate for construction costs for a possible second unit under the Future Baseline Condition. However, no additional facility construction costs are envisioned for TOD Alternative A (and thus in this analysis for TOD Alternative B as well).

Other Impacts: EMSD notes that transport time to metropolitan hospitals are short from Kaka'ako. They would be mainly to Queens and Straub, and a little further to Kuakini. Kaiser Health Care plans will be transported to Moanalua Kaiser.

7.2.4 Public Health – Medical Facilities

Assessment of impacts on medical facilities differs from other analyses in this chapter in that service is provided by a network of providers rather than a single agency. Most are private-sector providers, and so it is generally difficult and/or inappropriate to estimate costs that would be borne by government.

Medical facilities are of several types –

- Acute Care Facilities: These offer a wide range of medical, surgical, obstetric and pediatric services. These facilities primarily treat patients with conditions that require a hospital stay of fewer than 30 days.[30]

- Long Term Care Facilities: These may be defined as institutions that provide healthcare to people who are unable to manage independently in the community.[31] These are also known as "skilled nursing facilities" or "nursing facilities" and are either free-standing or hospital-based.

[30] Blue Cross Blue Shield Blue Care Network. [December 2013]. http://www.bcbsm.com/index/health-insurance-help/glossary.html

[31] Center for Disease Control and Prevention. [December 2013]. http://www.cdc.gov/HAI/settings/ltc_settings.html

- Specialty Care Facilities: These are acute care facilities that provide specialized services and specially trained personnel to care for a specific portion of the injured population, such as pediatric, burn injury, or spinal cord injury patients.[32]

Many of these facilities are run by the private sector, though with overall licensing supervision by the Hawai'i State Dept. of Health. Table 7.1 shows that the number of State-approved medical facilities has been declining since 2000:

Table 7.1: Number of State Approved Medical Facilities 2000-2010

Number of Facilities	Acute Care [a]	Long- term Care [a]	Specialty care	Total [b]
2000	24	45	24	74
2001	21	45	22	73
2002	20	45	23	72
2003	20	45	19	68
2004	22	47	20	70
2005	21	49	17	68
2006	19	43	13	62
2007	19	46	13	63
2008	19	46	14	66
2009	20	49	14	69
2010	20	48	15	70

Source: Hawai'i State Data Book. 2012. Table 2.25 Number and Bed Capacity of State-Approved Facilities, By Type of Facility 2000 2010. http://dbedt.hawaii.gov/economic/databook/db2012/

Notes: Excludes Tripler Army Medical Center. Figures based on facilities that reported their activity

[a] Acute/SNF swing beds are classified under long-term care.

[b] Institutions providing more than one kind of care are counted only once.

Present Conditions: Kaka'ako is not uniquely served by any one of the above types of health care facilities. It is part of the wider metropolitan Honolulu area currently served by numerous facilities, none of which (with the exception of a clinic associated with the John A. Burns School of Medicine) is now located in Kaka'ako itself –

- **Acute Care Hospitals** serving Kaka'ako and other parts of urban Honolulu include The Queen's Medical Center (a private non-profit facility, the largest hospital in Hawai'i, a trauma hospital, and part of The Queen's Health Systems), Kuakini Medical Center (a non-profit hospital that is part of Kuakini Health System), and Straub Clinic and Hospital (also a non-profit hospital under the Hawai'i Pacific Health System.

- **Long Term Care Facilities** serving the wider Honolulu area (including but not limited to Kaka'ako) include (a) Lē'ahi Hospital, which is a State-run nursing facility and tuberculosis hospital; (b) Kuakini Medical Center and The Queen's Medical Center, which also offer hospital-based skilled nursing services; (c) Maluhia; (d) Hale

[32] National Highway Traffic Safety Administration. 1996. *EMS Agenda for the Future*. Washington, D.C. [December 2013]. http://www.nhtsa.gov/people/injury/ems/emstraumasystem03/glossary.htm

Nani; (e) Oahu Care Facility; (f) Island Nursing and Rehab Center; and several other skilled nursing facilities.

- **Specialty Care Facilities** serving Honolulu/Kaka'ako include (a) Shriners Hospitals for Children-Honolulu, a pediatric orthopedic hospital providing care for children with bone, joint, and neuromuscular conditions; (b) Kapi'olani Medical Center for Women & Children, the state's only specialty care facility for women and children and only pediatric intensive care unit serving all islands and the Pacific Basin; and (c) The Rehabilitation Hospital of the Pacific, which provides rehabilitation services to patients with physical and cognitive disabilities.

- **Health Care Clinics** serving the area include the Waikīkī Health and Kalihi-Pālama Health Centers, both of which are federally-qualified health centers (FQHCs). FQHCs are organizations receiving grants under Section 330 of the Public Health Service Act (PHS). They receive reimbursement from Medicare and Medicaid, and supply comprehensive health services to underserved areas or populations based on a sliding fee scale.

- **Other:** Honolulu is also served by various health care providers such as home health agencies and hospices (which mostly provide care in people's homes), physician practices, urgent care clinics, and dialysis and rehabilitation centers.

The Healthcare Association of Hawai'i (HAH)[33] and the State Health Planning & Development Agency (SHPDA) [34] both report that the health care system throughout Hawai'i – in urban Honolulu and elsewhere – is currently stressed by various factors:

1. The shutdown in 2011 of two O'ahu hospitals (Hawai'i Medical Center East in Liliha and Hawai'i Medical Center West in 'Ewa). The closure of these hospitals, which employed 990 workers, eliminated more than 340 hospital beds. While ERs have been operating at capacity since these closures, the opening of The Queen's Medical Center-West O'ahu in May 2014 is thought to have relieved some of the systemic pressure by providing health services to patients who live on the Leeward side closer to their homes. The experts consulted could not quantify the impact of its opening, but did believe it is alleviating some of this stress.

2. The Great Recession, while technically ended, has left many without insurance and/or more complex health needs. Because of this, emergency rooms and community health centers face greater pressure.

3. Changes in the national health care system following the nation's health reform law enacted in March 2010 (i.e., the Affordable Care Act) are expected to increase

[33] Telephone conversation and email communications between JMK Assoc. Staff and Rachael Wong, Dr PH, Vice President and COO of Healthcare Association of Hawai'i (HAH) in December 2013 and February 2014. Additional email communication with Ms. Wong in October 2014.

[34] Information received via email communications between JMK Assoc. Staff and State Health Planning & Development Agency Director of Health Sue Radcliffe, MA in December 2013 and January 2014.

patient demand for and access to health care services. This could cause further stress on existing facilities.

None of these factors relate to population growth in any particular area, including Kaka'ako, but represent a challenge to the quality of health care both at present and also for the future growing population of Hawai'i in general.

Operational Impacts: Whether population growth takes place in Kaka'ako or elsewhere on O'ahu, the islandwide and statewide resilience of the health care system requires improvement. Population growth will otherwise continue to challenge the adequacy of health care throughout Hawai'i.

Because it cannot be currently estimated to what extent either TOD Alternative (A or B) will increase the population of the overall urban Honolulu on a net basis – i.e., because it cannot be known how many people would be living in urban Honolulu outside Kaka'ako under the Future Baseline Condition – it is difficult to estimate the impact on any current facility or on the network of facilities serving both Kaka'ako and the rest of urban Honolulu. No cost impacts can be calculated.

Facility Construction Impacts: The redirection of some population growth into Kaka'ako is highly unlikely to result in any publicly-funded facility construction costs in the area that would not occur anyway. At the moment, no such new construction is expected.

Other Impacts: From the viewpoint of adequacy of services, the system is now stressed and has the potential to be further stressed by population growth, whether in Kaka'ako, other parts of urban Honolulu, or the rest of the island.

7.2.5 Education

Present Conditions: As of late 2013, the State Dept. of Education's (DOE's) most recent available estimates indicate there are now (Fall 2012) about 450 students with Kaka'ako addresses in various public elementary, middle, and high schools serving the area.[35] Five schools from two complexes (Kaimukī and McKinley Complexes) serve Kaka'ako and surrounding urban areas. These are Royal and Ka'ahumanu Elementary Schools, Central and Washington Middle Schools, and President William McKinley High School, with recent enrollment figures shown in Table 7.2 below. These are all public schools operated by the DOE. Voyager Public Charter School, the area's only charter school serving grades K-8, recently relocated out of the area. Although there are more than 100 private pre-schools serving the Honolulu area (112), only 12 public pre-schools operate in Honolulu, none of which are located in Kaka'ako. There have, however, been recent proposals to open two new (private) pre-schools in Kaka'ako, including a Seagull Schools and a Montessori School. [36]

[35] This information and subsequent statements attributed to DOE derive from various communications (face-to-face, telephone, and written) between JMK Associates and personnel within the Planning Section, DOE Facilities Development Branch, October-November 2013.
[36] Pacific Business News. "Another school planned for Oahu's growing 'Third City' of Kaka'ako". Apr. 15, 2014. http://www.bizjournals.com/pacific/blog/2014/04/another-school-planned-for-oahus-growing-third.html

Table 7.2: Present and Recent Historic Enrollment in Schools Serving Kaka'ako

School	2006	2007	2008	2009	2010	2011	2012	2013

Source: DOE Facilities Development Branch

DOE representatives have confirmed that Royal Elementary and Queen Ka'ahumanu Elementary are currently operating at near capacity and may not be able to accommodate large surges in enrollment in the future. While DOE projections anticipate negative growth for both of the elementary schools as well as for Central Middle school over the next five years (and hence increasing capacity for future growth), Royal School is expected to have the ability to provide space for fewer than 30 additional children by 2018 under present conditions. (See Table 7.3)

Table 7.3: Current and Near-Term Future Anticipated School Capacity

	School Capacity[a]	2013-2014 Residual Capacity[b]	2018-2019 Residual Capacity[c]
McKinley Complex			
Royal Elementary	368	-8	29
Ka'ahumanu Elementary	623	26	79
Central Middle	843	492	587
McKinley High	2,012	335	199
Kaimukī Complex			
Washington Middle	1,210	416	354

[a] Maximum Enrollment. Capacity assessed in 2012-2013 via DOE's "ARTS Classroom Space Survey"
[b] 2012-2013 ARTS Classroom Space Survey less actual 2013-2014 Enrollment
[c] 2012-2013 ARTS Classroom Space Survey less projected 2018 Enrollment

The official DOE policy[37] regarding enrollment guidelines for new schools lays out standard student enrollment ranges and land acreage needed to accommodate them. The DOE recommends that elementary schools (grades K-5) serve 400-750 students on 8 to 15 usable acres;[38] that middle schools (grades 6-8) serve 500-1,000 students on 15-20 usable acres; and that high schools (grades 9-12) serve 800-1,600 students on 45-55 usable acres. Future schools will likely have the maximal capacities.

With this policy in mind, the DOE uses residential unit counts, as well as current enrollment to set student generation rates for a particular area. In the urban Honolulu

[37] State of Hawaii Board of Education. BOE Policies. 6000 Series. 6701. https://lilinote.k12.hi.us/STATE/BOE/POL1.NSF/85255a0a0010ae82852555340060479d/b31a0aa2c2ca52b10a2566a30082892f?OpenDocument
[38] According to DOE, "Useable is generally defined as land free of encumbrances determined to be unnecessary by the department of education, slope of five percent or less, with no ravines or stream beds".

area including Kaka'ako, the DOE has set student generation rates at 0.082 students per multi-family dwelling unit for elementary schools; 0.033 students per multi family dwelling unit for middle schools; and 0.054 students per multi family dwelling unit for high schools.

When measuring the impact of the development of additional units in Kaka'ako over area school facilities, it cannot be assumed that all of the pressure placed on those schools will come from the Kaka'ako area alone. The five schools mentioned above serve not only Kaka'ako, but surrounding areas as well. In fact, service areas for middle and high schools in particular serve a *much* larger area than Kaka'ako alone. However, it is not possible to know for certain what the growth will be in the remainder of these various school service areas.

Up until a few years ago, DOE believed that space would be made available for school facilities on the State-owned former Pohukaina School site, which is now proposed for an affordable housing project. The Pohukaina site is currently used for a State Library book processing center. The library is stated to move to an 'Aiea location by the end of the 2013-2014 fiscal year.

Operational Impacts: The DOE has developed various location-specific multipliers for estimating future student counts generated by new developments, intended for use in eventual impact fee calculations. The multipliers for the urban Honolulu area including Kaka'ako are based on area-wide estimates, not current Kaka'ako student enrollments. If applied to current Kaka'ako dwelling units, they would generate an estimated student count far in excess of the actual present student count. Use of these multipliers is thus likely conservative, in that they produce estimated future enrollments more substantial than might be derived from an extrapolation of present Kaka'ako conditions.

Based on these DOE multipliers, the number of students from Kaka'ako will increase significantly for build-out under the Future Baseline Condition and even more for build-out under TOD Alternatives A and B (see Table 7.4).

Table 7.4: Kaka'ako-Specific Impact on Students Served

	DOE Student Generation Rates (Per Unit)	Future Baseline Scenario[a]	TOD Alternative B[b]		TOD Alternative A[c]	
		# Students	# Students	Impact (Difference)	# Students	Impact (Difference)
Elementary	0.082	1,734	2,180	446	2,375	641
Middle	0.033	698	877	180	956	258
High	0.054	1,142	1,436	294	1,564	422
Total:		**3,574**	**4,493**	**920**	**4,896**	**1,322**

[a] Generation rate times dwelling units for build-out under Future Baseline, estimated to reach 21,146
[b] Generation rate times dwelling units for build-out under TOD Alternative B, estimated to be 26,588
[c] Generation rate times dwelling units for build-out under TOD Alternative A, estimated to be 28,968

The following operational cost estimate (Table 7.5) is based on the most recent overall DOE operating budget divided by total enrollment:

Table 7.5: Kaka'ako-Specific Impact on DOE Operational Costs

	Change in Students	Student Cost[a]	Total Annual Impact
TOD Altern. B	920	$11,854	$10,903,680
TOD Alern. A	1,322	$11,854	$15,670,015

[a] State of Hawaii DOE Financial Report. Office of Fiscal Services. July 1, 2010- June 30, 2011. http://www.hawaiipublicschools.org/DOE%20Forms/State%20Reports/FinancialReport2010-2011.pdf. Updated to 2012 dollars using Honolulu CPI.

It is to be remembered that both these expenditures and the change in student counts are expected to occur elsewhere on the island in any event – this "impact" is a *shift* or concentration into Kaka'ako.

Facility Construction Impacts: The student count figures in Table 7.4, when divided by maximum DOE school enrollments (considered appropriate by DOE Facilities Branch to use when considering future urban school sites) yield the following percentage equivalents of new schools needed at each level for various planning scenarios (Table 7.6) – *if* school district lines were redrawn such that Kaka'ako alone were to be the primary service area for schools:

Table 7.6: Kaka'ako Schools Needed Under Various Alternatives

	Max. Capacity for Schools	Future Baseline	TOD Alternative B		TOD Alternative A	
			Need	Impact (difference)	Need	Impact (difference)
Elementary	750	231%	291%	60%	317%	86%
Middle	1,000	70%	88%	18%	96%	26%
High	1,600	71%	90%	18%	98%	26%

Illustrative Explanation: Previously calculated Future Baseline student count of 1,734 elementary school students is equivalent to 2.31 times the number of students in one elementary school.

The table suggests that, under TOD Alternative A, build-out would generate enough students from Kaka'ako alone to fill more than three elementary schools and almost enough to fill one middle and one high school. Compared to build-out under the Future Baseline Condition, that is almost the equivalent of one additional one elementary school and fractions (about one-quarter each) of additional middle and high schools. For the lower-density TOD Alternative B, the impact numbers are equivalent to 60% of one elementary school and nearly one-fifth of additional middle and high schools.

However, because Kaka'ako is part of a larger DOE service area (particularly for middle and high schools), it is difficult to predict for certain at what point the need for any one particular new school would be generated – as that depends in part on growth in adjacent areas as well. That is, it is difficult to say to what extent actual DOE construction costs in future would depend *only* on Kaka'ako population growth.

The standard DOE approach – utilized in this analysis for costing purposes – instead uses *average* construction and land cost multipliers per dwelling unit, for various parts of the island. The following Table 7.7 uses DOE-supplied multipliers for urban Honolulu.

Table 7.7: Additional Kaka'ako-Specific School Facility Costs (DOE Multipliers)

FUTURE BASELINE ALTERNATIVE	Construction Cost	Land Cost	Combined Cost
Total Increase over Existing Units	*12,528*	*12,528*	*12,528*
Elementary[a]	$34,739,336	$62,312,823	**$97,052,159**
Middle[b]	$17,501,209	$18,465,843	**$35,967,051**
High[c]	$44,999,529	$104,305,702	**$149,305,231**
Total:	**$97,240,074**	**$185,084,367**	**$282,324,442**

[a] Elementary construction and land multipliers:	$2,773	$4,974	**Source for Multi-**
[b] Middle school construction and land multipliers:	$1,397	$1,474	**pliers:** Hawai'i
[c] High School construction and land multipliers:	$3,592	$8,326	State DOE

It suggests that DOE would have to spend a little under $123 million more for construction and land costs under TOD Alternative B, and $176 million more under Alternative A, than under the Future Baseline Condition.

Again, however, it should be remembered this means the DOE would need to spend this money in Kaka'ako rather than elsewhere on the island, as both alternatives are about redirecting population to Kaka'ako. Additionally, these Kaka'ako-specific facility costs, as well as all preceding Kaka'ako-specific impact numbers, are likely somewhat overstated because some of the additional units (and their student counts) estimated to be developed at build-out of each alternative and could, under the Future Baseline Condition, instead still be developed in the same DOE school service areas near to Kaka'ako. Thus***, similar DOE calculations would apply to growth wherever it occurs on O'ahu.***

Other Impacts: Probably the most important actual consequence of Kaka'ako population growth for school development is the need to find land for new schools. This is an issue facing DOE in all areas now being planned or considered for higher-density TOD uses. DOE has yet (at the time of this writing) to initiate any comprehensive analyses to identify potential sites in Kaka'ako or other TOD areas, and has not conducted any in Kaka'ako for at least the past decade. However, there are no currently known candidate sites in Kaka'ako itself. A further constraint in Kaka'ako is that the Makai area (below Ala Moana Blvd.) is ruled out for DOE use because this area is largely in the potential tsunami inundation zone.

It is no more certain that additional candidate sites could be identified close to Kaka'ako than in Kaka'ako itself. However, if such a solution were to be found feasible – i.e., continuing to send Kaka'ako students to schools bordering the area, as is now the case – this could arguably affect the sense of community within greater Kaka'ako or its constituent neighborhoods.

According to DOE:

> As late as December 2011, the DOE was operating with the understanding that space would be made available for a school facility within whatever development project took place on the former Pohukaina School site.
>
> Per HRS302A-1601 the DOE is authorized to collect land and money from developers of residential housing through the imposition of impact fees. The fee formula is set in law and is heavily weighted towards providing the land (or cost of land) needed for new schools with just a 10% contribution toward construction costs. (The legislative intent was that the balance of construction funds would come from state funds.) To date, the formula has been used principally on suburban-style projects with large undeveloped acreage.
>
> The formula has not yet been applied in high density urban areas, where there is limited land and the cost of the land is much higher. Because of the cost of land associated with urban development, it is expected that the impact fee formula would yield a higher per unit cost in developing urban areas such as Kaka'ako.
>
> The impact fee formula, as stated in law, assumes that a new residential project will have an impact on student enrollment at elementary, middle and high schools. In Kaka'ako, there is an unusual situation of insufficient space in the elementary schools that serve the area, but currently significant capacity in the middle schools and some limited additional space in the high school. It is unclear at this point if a legal interpretation of the impact fee law would permit application of only those portions of the formula that are needed (i.e. fees charged based on providing elementary school capacity only).
>
> The DOE would need to determine if this exception would be possible and then what the scenario might be should future capacity be required in middle and high schools if Kaka'ako continued to develop.

7.2.6 Parks and Recreation

Present Conditions: There are currently seven (7) public parks in Kaka'ako occupying nearly 54 acres of land. Both the Mother Waldron Neighborhood Park and the Kawaiaha'o Street Mini Park are managed by the City and County of Honolulu's Department of Parks and Recreation (DPR), while the rest are managed by HCDA. No Kaka'ako parks are managed by the State Parks Division of the Dept. of Land and Natural Resources. Private recreational facilities associated with particular buildings provide another 16 acres in the area. (See following Table 7.8.) In addition, DPR's Ala Moana Regional Park abuts the District on the east and serves as a regional park for greater Honolulu. Historic Thomas Square abuts the district on the north.

Table 7.8: Public and Private Recreational Facilities in Kaka'ako

Public Recreation	Agency/Mgnt	Acres
Mother Waldron Neighborhood Park	City DPR	2.73
Kolowalu Park [a]	State HCDA	2.57
Restaurant Row Park	State HCDA	1.79
Kawaiaha'o Street Mini Park	City DPR	0.2
Kaka'ako Gateway	State HCDA	2.2
Kaka'ako Waterfront Park [b]	State HCDA	38.9
Kewalo Basin Park	State HCDA	5.2
Total:		**53.59**
Private Recreation	**Agency/Mgnt**	**Acres**
One Waterfront Plaza and Towers	Private	0.77
Pacific Park Plaza	Private	0.94
404 Pi'ikoi	Private	4.98
Imperial Plaza	Private	0.44
Kamakee Vista	Private	0.53
Pohulani	Private	0.95
Kauhale Kaka'ako	Private	0.68
Na Lei Hulu Kūpuna	Private	0.07
Honuakaha	Private	0.39
One Archer Lane	Private	0.44
Hokua	Private	1.89
Moana Pacific	Private	2.17
909 Kapi'olani	Private	0.47
Keola Lai	Private	0.46
Pacifica	Private	0.62
680 Ala Moana	Private	0.29
Total:		**16.09**

[a] Kolowalu Park (sometimes referred to as Queen Street Park) was developed by HCDA with thoughts to possibly convey it to DPR upon legislative approval. However this has been delayed because of issues with encroachment of adjacent buildings on the park site.

[b] Park-zone land, including Look Lab site

Source: HCDA. 2014. http://dbedt.hawaii.gov/hcda/files/2014/04/kcdd-park-and-private-recreation-space-032714.pdf

Current HCDA rules require that 55 SF of recreational space be allocated per dwelling unit developed in Kaka'ako. The City and County of Honolulu standards call for 110 SF of green space[39] per dwelling unit for any high rise multi-family or town house development anywhere on the island. While under these City standards, the provision of green areas within Kaka'ako has currently been met, it should be noted that the Mauka Area Rules (HAR Chapter 22 §15-217-8) state that "Recreational space" means an outdoors or indoors open space within a development that can be located at any level and is available for recreational use. It is hence limited not only to green space, parks, or playgrounds, but can also include parking areas.

In discussions for this study, DPR expressed concerns regarding the current inventory of parks and adequacy of their uses in the area.[40] DPR said the need in Kaka'ako is not for small private parks sprinkled throughout the region (primarily *passive* uses), but for larger regional *active* green spaces with potential to provide sports fields. While Kaka'ako Waterfront Park offers passive recreational uses (such as picnicking, strolling, and jogging), its terrain is too hilly to provide suitable outdoor space for baseball, lacrosse, and other active team sports. The limited availability of land in Kaka'ako will not allow for another regional park to be built in Kaka'ako.

However, it is HCDA's position that the nearby Ala Moana Regional Park is sufficient to meet the future needs of Kaka'ako's growing population. HCDA also recognizes that private landowners may be interested in providing active recreational space in new developments in the form of fitness centers or clubs to supplement existing parks. Contemporary facilities such as these do not rely upon the availability of large open grassed areas. The privately funded Kroc Center in East Kapolei has been immensely successful and offers a good example of a non-traditional active recreational facility.

Operational Impacts: Neither the State HCDA (the primary provider of parks and recreational facilities in Kaka'ako) nor the City DPR currently plans to construct additional parks in or near Kaka'ako, suggesting that impacts on existing public facilities will be confined to those listed at the start of Table 7.8, and other nearby regional facilities. However, HCDA plans to develop a Parks Master Plan that would thoroughly study needs and best ways to meet them. ***Until such a study is completed, recreational impacts remain an "Unresolved Issue."*** Nevertheless, an obvious provisional conclusion is that there is potential for congestion at area public parks and a limited supply to meet public demand within Kaka'ako – particularly in regard to sports fields and playgrounds, a recreational need that has historically not yet been met by requirements for developer contributions.

It is also difficult under present conditions to quantify financial impacts on affected agencies for operations. Even if no new public facilities are provided, as per current

[39] According to the City and County Land Use Ordinance (Chapter 22 §22-7.5), this requirement is to land area specifically dedicated for parks and playgrounds.

[40] Information attributed to DPR is derived from various communications (telephone and written) between JMK Associates and John Reid, staff planner within the City and County of Honolulu's Department of Parks Recreation, November-December 2013.

plans, HCDA believes that population growth in Kaka'ako would result in need for additional parks personnel but would little impact any other portion of the budget. Under such conditions, the need for additional maintenance personnel would likely be marginal rather than directly proportional to area population growth – i.e., even if three times as many people live or stay in Kaka'ako in the future as do today, and no new parks are provided, that would not mean that current parks would require three times the number of maintenance workers. However, HCDA has no way to estimate the required number of additional workers, and JMK Associates could find no reasonable basis for estimates of our own.

Similarly, DPR staff had no estimates of financial impacts on future operational costs (for the Future Baseline or either of the TOD Alternatives) for their current two small Kaka'ako parks. DPR believes that – unless the proposed Kaka'ako Parks Master Plan leads to development of more active public or private recreational facilities – the greater impact of Kaka'ako population growth on public facilities would be increased pressure on nearby Ala Moana Regional Park. Again, DPR had no estimates of cost impacts for either future growth scenario, nor could JMK Associates determine its own basis for estimating cost implications.

Facility Construction Impacts: As previously stated, no additional public parks are planned under either the Future Baseline or either of the proposed TOD Alternatives. Therefore, the current estimated publicly-funded park facility cost impact is $0. Again, though, the social impacts of overcrowded parks and/or lack of active sports on Kaka'ako facilities could be significant.

Also as previously noted, HCDA has plans to develop a Parks Master Plan for Kaka'ako. Part of the intent for such a Plan would be to maximize uses of Kaka'ako Waterfront Park and to provide residents and visitors with more active recreational opportunities within the park. Ideas being entertained for the Waterfront Park include a possible indoor sports facility, as well as outdoor basketball courts. However, nothing can be said at this time regarding cost impacts or funding mechanisms. Developer fees would likely be involved, but whether public taxpayer subsidies would also figure in – or to what extent – is currently unknown.

As a result of a public-private partnership with local developer Stanford Carr Development, LLC (SCD), improvements at the Mother Waldron Neighborhood Park were recently completed (Sept. 2014). The restoration (funded from unutilized private funds from a nearby SCD development) includes a new basketball court and playground, as well as new landscaping and trees, and the restoration of the comfort station and pavilion.

Similarly, in their conceptual planning process, HCDA planners have noted that future redevelopment of the Neil S. Blaisdell Center by its owner, the City and County of Honolulu, could accommodate a sizeable open space area that could be used for park purposes.

Private recreational space, or at least open space, will be built according to HCDA's current standards of 55 SF of green space per one dwelling unit constructed. Private developers will be responsible for managing their own green space. Green space allocation per dwelling unit under these standards is presented here under the Future Baseline Condition as well as the two proposed TOD Alternatives (A and B):

- 12,528 additional units under current Rules – i.e., the Future Baseline Condition – times 55 SF equals 689,024 additional SF of green space (about 16 acres).
- Above and beyond the Future Baseline Condition, build-out of TOD Alternative B would create a further 5,513 units and demand for another 303,228 SF of green space (about 7.0 more acres). This difference is the impact for Alternative B.
- Above and beyond the Future Baseline Condition, build-out of TOD Alternative A would create a further 7,892 units and demand for another 434,084 SF of green space (about 10.0 more acres). This difference is the impact for Alternative A.

More than eight acres of public outdoor recreational space have been proposed in the already approved Howard Hughes Corp.[41] and Kamehameha Schools Master Plans[42] (Table 7.9), representing a substantial but still partial response to the total demand, according to the above standards and calculations for the total additional 16 acres under the Future Baseline Condition, 23 acres under TOD Alternative B, and 26 acres under TOD Alternative A.

Table 7.9: Proposed Public Outdoor Recreation Space

Proposed Public Outdoor Recreation Space from Ward (Howard Hughes) and KS Master Plans	Acres
Ward Neighborhood Central Plaza	3.44
Ward Neighborhood Ewa Plaza	1.00
Ward Neighborhood Diamondhead Plaza	1.00
Park to Park Connection on Cooke Street	2.02
Auahi Street Community Gathering Place	0.57
Total:	**8.04**

7.2.7 Public Infrastructure

Public infrastructure costs for the Future Baseline Condition are found in past HCDA studies cited in Table 7.10, which also shows updated dollar values and a few adjustments explained below. Two other EIS team members – Belt Collins Hawai'i LLC and Nelson\Nygaard Consulting Associates, Inc. – produced separate analyses of Kaka'ako-specific infrastructure impacts, and provided JMK Associates with the following information.

[41] Howard Hughes Corp. *A Vision for Ward.* http://www.avisionforward.com/
[42] Kamehameha Schools Kaka'ako Website. http://www.ourkakaako.com/

City Transportation-Related Costs: For TOD Alternative A (subsequently attributed to Alternative B as well), Nelson\Nygaard estimates total transportation-related "mitigation" costs would be some $14,433,000 in 2015 dollars (roughly $13,331,000 in 2012 dollars). However, most of these consist of required pedestrian improvements that will likely be passed on to developers. Nelson\Nygaard suggests that bicycle-related improvements are most likely to be funded by the City Dept. of Transportation Services (with no cost to the State), as well as the proposed Ala Moana Blvd. "Share Use Path" for pedestrians. They estimate these as totaling $3,178,000 in 2015 dollars (roughly $2,935,000 in 2012 dollars).

Table 7.10: Public Infrastructure Costs for Future Baseline Condition

Mauka[a]	Amount in 2008 Dollars	Amount in 2012 Dollars[d]	2014 Adjustments[e]
Sewer	$49,482,000	$53,938,733	$3,253,120
Water	$5,140,000	$5,602,948	$46,978,873
Water Main Replacement	$249,800	$272,299	
Storm Drain	$6,666,000	$7,266,392	$7,266,392
Street Improvements	$20,780,000	$22,651,608	$22,651,608
Traffic Signalization	$600,000	$654,041	$654,041
Street Lighting	$5,140,000	$5,602,948	$5,602,948
Pavement Patching Repair	$2,538,990	$2,538,990	$2,538,990
Mauka Sub-Total	**$90,596,790**	**$98,527,960**	**$88,945,972**
Makai[b]	**Amount in 2005 Dollars**	**Amount in 2012 Dollars[d]**	**2014 Adjustments[e]**
Water Supply	$1,470,000	$1,854,028	$1,854,028
Waste Water	$2,880,000	$3,632,382	$3,632,382
Roads	$10,520,000	$13,268,284	$13,268,284
Traffic Signals[c]	$87,090	$109,842	$109,842
Street Lighting[c]	$746,110	$941,027	$941,027
Design Fees	$3,400,000	$4,288,229	$4,288,229
Makai Sub-Total	**$19,103,200**	**$24,093,790**	**$24,093,790**
Total Kaka'ako	**$109,699,990**	**$122,621,750**	**$113,039,762**

[a] M&E Pacific, Inc. 2009. "Kakaako Community Development District Mauka Area Infrastructure Plan." Appendix E, Vol. III, *Final Supplemental Environmental Impact Statement, Draft Mauka Area Plan.* Prepared by EDAW, Inc. for HCDA. Pp. 16-1 to 16-10. Also contains cost estimates for Electrical, Telephone, and Cable TV not included here because not taxpayer-funded, but used to estimate some Makai costs.

[b] HCDA. 2005. *Kakaako Community Development District Makai Area Development Plan.* P. 43. Original showed a total (no breakdown) 2005 figure of $8.6M in (2005 $s) for "Power, Communications, Street Lighting, Traffic Controls."

[c] Separate costs for these items estimated from the original $8.6M by percentages of similar total in 2009 Mauka Area Infrastructure Plan above.

[d] Calculated by JMK Associates, Inc., using Honolulu Consumer Price Index (CPI).

[e] 2014 Adjustments (in orange-shaded cells) provided by Belt Collins Hawai'i based on consultations with City agencies, and converted to 2012 $s by JMK Associates, using Honolulu CPI. Large differences between 2009 EIS and 2014 adjustments for Water and, particularly, Sewer are explained in Belt Collins report for this EIS.

Water and Sewer (Wastewater): Based on discussions with City agencies, Belt Collins provided (a) the adjusted Future Baseline figures highlighted in Table 7.10; and (b) estimated additional infrastructure costs for each of the two TOD Alternatives (though these numbers proved identical). These estimated costs (all adjusted to 2012 dollars) are shown in the following summary Table 7.11 for Alternative B and Table 7.12 for Alternative B. (Both tables also show the Nelson\ Nygaard "Transportation Improvements" figure under "Infrastructure – City and County of Honolulu Agencies.")

7.2.8 Summary of Kaka'ako-Specific Costs

Table 7.11 and Table 7.12 summarize foregoing cost information, and also provide estimates of direct construction job-years associated with Kaka'ako-specific facility/ infrastructure impacts. Again, many of these costs will be incurred wherever else on O'ahu (outside Kaka'ako) that future growth in population and/or economic activity would occur under the Future Baseline Condition. The following Section 7.3 considers the net islandwide public costs attributable just to the growth-*inducing* aspects of the TOD Alternatives, as opposed to the growth-*capturing* aspects primarily analyzed here.

Table 7.11: Summary, Kaka'ako-Specific Cost Impacts of TOD Alternative B

	One-Time Construction, Equipment		Annual Operations	
	Nature of Cost	Amount	Nature of Cost	Amount
FACILITIES				
City and County of Honolulu Agencies				
Fire Department	Second fire station, 2 trucks	$10,500,000	Additional Personnel	$2,618,240

[b] Though DOE cost figures here include Land Acquisition, job estimates based on Construction costs only.

7.3 Islandwide Impacts

This section begins a transition in this report to studying the *net islandwide impacts* of the TOD Alternatives (A or B). As explained in the report's opening chapters (Sections 1.6 and 2.5), these effects are less than the Kaka'ako-specific impacts, because incremental residential population growth in Kaka'ako resulting from the TOD Alternatives would likely occur somewhere on the island under either TOD Alternative A or Alternative B.

The primary component of either TOD Alternative considered to be "net new islandwide impacts" would be the three hotels, along with the visitor population and associated islandwide employment and dependents of employees supported by visitor expenditures. Associated public costs set forth here are also islandwide impacts.

As will be established in the following Chapter 8, Section 8.2.2, the combined resident and visitor de facto islandwide population impact is estimated for TOD Alternative A as 7,423 average daily population (2,364 new Kaka'ako hotel guests or part-time residents, with the rest comprised of worker households distributed throughout the island). For TOD Alternative B, the comparable figures are 6,768 total (including 2,106 hotel guests or part-time residents). These are conservative numbers for establishing islandwide public service impacts, because they assume that residential workers and dependents represent entirely new or "created" population – in reality, some of the residential population might already be on-island but simply "maintained" by expanded employment opportunities.

All statements in this section flow from the same agency sources and procedures described above for Kaka'ako-specific impacts. A more concise format is possible because the Future Baseline Condition need not be addressed. It involves zero hotels and a fixed base level of part-time visitors. Impacts on public services and facilities can be directly derived from the dwelling unit or population impacts of each TOD Alternative (calculated in the following Chapter 8), and these would be dispersed islandwide.

7.3.1 Public Safety – Fire Department

Operational Impacts: For TOD Alternative A, according to the HFD, the additional net islandwide population would generate a need for three additional on-duty firefighters (nine total, to cover all shifts), one support staff, and probably no new equipment. At current average salaries, the annual additional personnel cost would be a little under $820,000. The same impact is conservatively assumed for TOD Alternative B

Facility Construction Impacts: For both proposed Alternatives, none would be required due just to the limited operational impacts described above. It should of course be acknowledged – for all public agencies discussed in this section – that small population increases from any one project contribute over time to new facility and infrastructure needs, but it may still be correctly stated that this particular project will have a negligible effect on such demand.

7.3.2 Public Safety – Police Department

Operational Impacts: Applying the previously described ratio of 8.9 officers per 10,000 de facto population (with average cost of $96,000 each for salaries plus support costs) to the projected de facto populations calculated in the following Chapter 8, the net islandwide impact at full build-out would be about 6.0 additional police offers and $578,000 additional personnel costs annually for TOD Alternative B. For TOD Alternative A, it would be about 6.6 additional officers and $634,000 additional personnel cost annually.

Facility Construction Impacts: HPD does not project any facility construction need due to islandwide impacts of TOD Alternative A, and the slightly lower-impact TOD Alternative B would logically not create any facility construction needs either.

7.3.3 Public Health – Emergency Services

Operational Impacts: According to City budget documents, the total actual FY2012 EMSD budget was $24,181,985. Dividing this number by the 2012 de facto population of 1,019,156 yields a per-capita service cost of $23.73. For TOD Alternative B, that number times the de facto population increase of 6,768 produces about $161,000 in 2012 dollars. For Alternative A, $23.73 times a de facto population increase of 7,423 generates an annual impact of about $176,000 in 2012 dollars. Again, this difference in estimates is not meaningful in any practical terms.

Facility Construction Impacts: Given the relatively small islandwide population increase, this would be zero for either of the proposed Alternatives.

7.3.4 Public Health – Hospitals and Health Care Facilities

Operational Impacts: As discussed previously in Section 7.3.4, the overall Hawai'i health care system is currently stressed due to a number of factors. Any resident or visitor population growth at all will definitely add to that stress. However, the net islandwide growth attributable to either TOD Alternative A or Alternative B is unlikely to be significant, relative to overall population growth trends.

Facility Construction Impacts: No Kaka'ako-specific facility construction impacts are anticipated, and the net islandwide de facto population growth from either alternative is not sufficient to require any specific facility construction elsewhere on the island.

7.3.5 Education

Operational Impacts: As with other agencies, it is assumed that the Kaka'ako-specific operational impacts are *not* part of the net islandwide impacts, because the TOD Alternatives do not cause creation of housing or population on O'ahu that would not otherwise take place – it would simply attract more of it to Kaka'ako.

For purposes of this analysis, the relevant project impacts that would affect public education would consist of an estimated 5,354 full-time residents directly or indirectly supported by jobs associated with new hotels and part-time residents in Kaka'ako under TOD Alternative A (4,934 under TOD Alternative B), and conservatively assumed not to be part of the island's population base under the Future Baseline Condition. (See calculations in subsequent Table 8.3.) These residents would be distributed throughout the island.

Given an assumed average household size of 2.95 (see Figure 2.3), this implies 1,816 O'ahu households created or maintained under TOD Alternative A, and 1,673 households under Alternative B. The procedure for estimating student counts involves application of DOE multipliers, as was done in the Kaka'ako-specific analysis (see preceding Table 7.4). However, the multipliers used there were specifically for multi-

family units in urban Honolulu, and DOE multipliers for other unit types and/or other locations tend to be higher. Because DOE has no generic islandwide average multipliers, JMK Associates (with tentative concurrence of DOE) has boosted the multipliers used in Table 7.4 by 15% to approximate an islandwide average, though has retained the same estimated per-student cost. With these assumptions, the islandwide operational impacts equate to an additional 353 students and $4.18 million annual operational cost for TOD Alternative A and 325 students and $3.85 million for TOD Alternative B (see Table 7.13).

Table 7.13: Islandwide Operational Impacts on Schools

Islandwide Impact on Schools, by Alternative		Adjusted Student Generation Rates	Islandwide Students Generated	Average Per-Student Cost	Total Annual Impact
TOD Alternative B	Elementary	0.094	158		
	Middle	0.038	63		
	High	0.062	104		
	Total:		**325**	**$11,854**	**$3,852,016**
TOD Alternative A	Elementary	0.094	171		
	Middle	0.038	69		
	High	0.062	113		
	Total:		**353**	**$11,854**	**$4,181,465**

Facility Construction Impacts: The logic used by DOE and the logic used elsewhere in this analysis for other agencies differ. Other agencies did not assume the relatively small net islandwide population impacts would generate facility costs of any magnitude that could be calculated.

However, the DOE (and the foregoing analysis in Section 7.2.5) uses average multipliers per dwelling unit in Kaka'ako, and so the islandwide analysis here will follow suit. However, the multipliers for this purpose are associated just with units producing the 353 new students (TOD Alternative A) and 325 new students (Alternative B) in Table 7.13.

Exact DOE multipliers for dwelling units change according to location and unit type – both of which are unknown for the islandwide population and housing unit impacts. As per discussion with DOE, JMK Associates in the following Table 7.14 uses the same construction cost multipliers previously used in Table 7.7 for Kaka'ako-specific calculations, but reduces the land cost multipliers by an estimated 15% to recognize lower land costs outside the urban core. Table 7.14 suggests an islandwide facility cost impact of about $34 million for TOD Alternative B and nearly $37 million for TOD Alternative A.

Table 7.14: Islandwide School Facility Costs (DOE Multipliers)

ALTERNATIVE B: IMPACT (DIFFERENCE)	Construction Cost	Land Cost	Combined Cost
Change in Units over Future Baseline	*1,672*	*1,672*	*1,672*
Elementary[a]	$4,636,456	$7,069,049	$11,705,505
Middle[b]	$2,335,784	$2,094,849	$4,430,633
High[c]	$6,005,824	$11,832,911	$17,838,735
Total:	***$12,978,064***	***$20,996,809***	***$33,974,873***
ALTERNATIVE A: IMPACT (DIFFERENCE)	**Construction Cost**	**Land Cost**	**Combined Cost**
Change in Units over Future Baseline	*1,815*	*1,815*	*1,815*

7.3.6 Parks and Recreation

Operational Impacts: Islandwide operational cost impacts for parks and recreation are borne primarily by the City DPR, but potentially also by the State Parks Division of the State DLNR.

According to DPR staff, additional net islandwide population would naturally mean more people will use O'ahu parks. However, DPR was unable to determine how this increase in use would generate the need for additional personnel, increase the need for park maintenance and thus impact the overall operating cost.

JMK Associates developed its own rough assumptions for these operational cost impacts. First, we assume the small magnitude of the net islandwide population increase would generate limited overall operational impact, primarily cost for additional personnel. We then assume these personnel impacts would be similar to those for the Honolulu Fire Department, an agency with roughly the same number of funded positions for Fiscal Year 2012 (although HFD salaries are higher than those for DPR). Note that this is a conservative assumption, because the HFD estimate of additional personnel needed for the islandwide population impact exceeded that of the much larger Honolulu Police Dept.

First, we adapted the HFD's assumption of ten total additional personnel needed for the islandwide population increase under either TOD Alternative A or B. DPR's FY2012 budget [43] was then used to calculate the cost of adding these additional City workers, by dividing the amount authorized for salaries ($38,039,036) by the authorized number of positions at DPR (1,157.65). This results in a cost per worker of $32,859. The cost impact for both TOD Alternative A and B would thus be about $328,590.

[43] City and County of Honolulu. *Departmental and Agency Reports of the City and County of Honolulu for Fiscal Year July 1, 2011 to June 30*. http://www1.honolulu.gov/csd/wholebook.pdf.

Small net islandwide operational impacts on State parks would fall to the DLNR's State Parks Division rather than HCDA, whose responsibilities are largely confined to Kaka'ako. The Director of the State Parks Division said the small estimated increase in net islandwide population is not likely to impact on State parks located on O'ahu. He noted that "State Parks, unlike County Parks, aren't created based on population, rather they are natural or cultural resource based." [44]

Facility Construction Impacts: Islandwide facility costs would be attributable to any additional facility costs due to net islandwide population increase. However, the net islandwide population increase is sufficiently small that this second component is likely to be zero for both Alternatives.

7.3.7 Public Infrastructure

Incremental islandwide population increase related to the three hotels and additional part-time residents under either TOD Alternative A or B is not seen as likely to strain public infrastructure. While cumulative impacts of small increments of population eventually create do create infrastructure needs, the population levels assessed here are sufficiently small that the cost may be appropriately be equated to $0.

7.3.8 Summary of Islandwide Costs

Table 7.15 and Table 7.16 summarize foregoing cost information, and also provide estimates of direct construction job-years associated with islandwide facility/ infrastructure impacts.

[44] Email Communication with Dan Quinn, Director, DLNR, Division of State Parks. Oct. 14, 2013.

8. RESULTS: ISLANDWIDE ECONOMIC IMPACTS

This chapter provides estimates of islandwide impacts. As discussed in the foregoing chapter on "Methods and Assumptions" (particularly Section 1.6), islandwide impacts are actually substantially *smaller* than Kaka'ako-specific impacts, because they are based only on project elements that are assumed not to occur somewhere on the island – whether in Kaka'ako or elsewhere – if transit-oriented development is not implemented in Kaka'ako:

- Construction and operation of three hotels (illustrative hotel types including a full-service hotel for travelers desiring to stay outside Waikīkī, a business-oriented hotel; and a condo-hotel);
- Initial expenditures by an increased number of part-time residents to furnish and accessorize units, as well as large purchases by some for automobiles (these initial one-time expenditures counted along with construction impacts) and ongoing average annual expenditures by part-time residents (counted with operational impacts);
- Construction of additional government public facilities and/or infrastructure required by population growth and development associated with the above factors.

Islandwide impacts thus represent a simpler situation, and consequently this chapter differs from earlier chapters on Kaka'ako-specific impacts as follows:

1. Construction and operational impacts are both contained here in the same chapter.
2. The calculations can be more fully shown in straightforward tables that include assumptions and intermediate steps – something that could not be readily done for Kaka'ako-specific results summing up hundreds of individual calculations (some of which included logical "If-Then" commands and not just multiplication, addition, etc.).
3. Rather than calculating overall results separately for the Future Baseline Condition and each TOD Alternative, and *then* subtracting to get impacts, the simpler analysis here *begins* with the difference (impact) in direct output for each element, and then applies multipliers to determine associated impacts such as islandwide employment, earnings, etc. This procedure yields mathematically identical results but is more succinct. Most of the difference flows from TOD components – Future Baseline values would all be zero, except for some part-time resident spending.

8.1 Construction-Related Islandwide Economic and Population Impacts

Islandwide construction impacts flow from development of three hotels and the various public facilities and infrastructure increments discussed in Chapter 7, along with initial expenditures by part-time residents to prepare their new homes for occupancy.

8.1.1 Methods and Caveats

A full and detailed explanation of methods and assumptions was provided earlier in Section 2.6, which explains the difference in "direct" versus "total" impacts and also discusses the very rough and preliminary nature of the component dealing with part-time residents' initial expenditures. It further notes that these are cumulative results over time for the difference in full build-outs of both scenarios.

Also as noted there, economic and population impacts should be interpreted as economic effects "created or maintained" – if no other part of the economy is in decline, these would be money, jobs, and population *in addition* ("created") to then-current levels, but if some other economic activity is fading, the results show the money, jobs, and population *preserved* ("maintained") by the project, on a net islandwide basis.

8.1.2 Results

Table 8.1 and Table 8.2 show the calculation process and results. Each begins with the key inputs of dollars spent in the Hawai'i economy. For hotels, these were calculated by methods and assumptions set forth in Chapter 2, Section 2.4. For public facilities and infrastructure, they reflect figures from Chapter 7. For part-time resident initial spending, they were calculated by methods and assumptions set forth in Section 2.6. The tables show the multipliers used from the Hawai'i Inter-County Input-Output (I-O) Model, and also show some interim results used in the following Chapter 9 analysis of government cost-revenue fiscal impacts.

Output (Economic Activity): Due to the circulation of money through the economy (multiplier or "ripple" effects), for Alternative B, the initial direct output increment of about $235 million would result in a total $496 million in overall sales, payments, and exchanges (i.e., that much *more* under Alternative B than the Future Baseline Condition). For Alternative A, the total statewide economic impact is $474 million.

Earnings: Of this additional economic activity, for Alternative B, about $75 million would be for direct household earnings of construction workers, supporting professionals, and retailers. With the multiplier effects, the total earnings come to about $150 million. For Alternative A, comparable figures are $73 million and $144 million.

Jobs (Job-years): Full build-out under Alternative B would create or maintain about 960 more job-years of direct employment than would full build-out of the Future Baseline Condition – with multiplier effects, total job-years of employment reaches about 2,660. For Alternative A, comparable figures are about 1,075 and 2,680.

Population Impacts: A relatively small proportion of direct construction workers would likely come from off-island, but the on-island direct workers plus indirect/induced workers would support a total population (themselves and dependents) of about 4,935 at build-out – again, this much *more* created or maintained under TOD Alternative B than under the Future Baseline Condition. For Alternative A, the result is almost the same at nearly 5,010.

[1] Hard/soft cost distinction not applicable to initial expenditures by part-time residents, though retail multipliers shown in "Hard Cost" multiplier rows for visual convenience. [2] General Excise Tax (GET) calculated as 0.5% of direct of total County output (about 96% of Statewide). [3] Assumed average of 20% of direct construction from off-island. [4] At 1.976 population-to-worker ratio.

8.2 Operations-Related Islandwide Economic and Population Impacts

Operational impacts discussed here are on an *annual* basis, and flow entirely from new hotel guest spending and the additional annual expenditures of the incremental part-time resident population (i.e., additional numbers present under either of the TOD Alternatives, A or B, compared to the Future Baseline Condition).

8.2.1 Methods and Caveats

See Chapter 2, Section 2.7 for a detailed discussion of methods and assumptions, including explanation of "Visitor Expenditure" (VE) and "Personal Consumption Expenditure" (PCE) multipliers and caveats about the differences in assumed hotel unit counts. That section also includes preliminary calculations for estimated average daily expenditures, which provide a starting point for this analysis.

Calculations again begin with increments from the Future Baseline to each TOD Alternative, and apply multipliers to these differences. Values for the Future Baseline Condition alone would be zero, except for some part-time resident spending.

8.2.2 Results

Table 8.3 shows how earlier results are combined to estimate change from the Future Baseline Condition to TOD Alternative B in the key input of total annual expenditures. It indicates values of various VE and PCE multipliers from the I-O Model, and indicates interim results used in the following Chapter 9 analysis of fiscal impacts. Table 8.4 does the same for TOD Alternative A.

Output (Economic Activity): After build-out, the project under TOD Alternative B is estimated to generate about $180 million more in direct output annually than under the Future Baseline Condition. With multiplier effects, the difference in total output would be about $324 million, mostly attributable to spending by hotel guests.

For TOD Alternative A, the direct output impact is about $197 million, and total output impact about $351 million. TOD Alternative A thus generates impacts about 8% - 10% higher than TOD Alternative B.

Earnings: Earnings flowing to households would be about $48 million more under TOD Alternative B than under the Future Baseline Condition due to direct visitor and part-time resident expenditures; about $94 million total impact with multiplier effects annually.

Results for TOD Alternative A are again about 8% greater – direct earnings of $52 million and total with multiplier effects of about $101 million annually.

J·M·K John M. Knox & Associates, Inc. Oct. 15, 2014

Jobs (Full- and Part-Time): Direct jobs created or maintained by new hotel guest and additional part-time resident spending would be about 1,200 more under TOD Alternative B. (Note that these direct jobs are *islandwide*, because visitor expenditures are not limited to Kaka'ako.) With multiplier effects, the total job impact is estimated at about 2,500 – again, mostly attributable to hotel guest expenditures.

For TOD Alternative A, comparable figures are a bit over 1,300 direct and 2,700 total, impact figures about 8% - 9% greater than for TOD Alternative B.

Population Impacts: Total additional employment would support a full-time resident population of about 4,930 people (workers plus dependents) more under TOD Alternative B than under the Future Baseline Condition. Subtracting average off-island resident population and adding the visitor population, the total de facto population impact would be nearly 6,760.

Results for TOD Alternative A are 9% - 10% higher – about 5,350 resident population and about 7,425 total de facto population.

All of these impact figures – output, earnings, jobs, and population – represent amounts "created *or* maintained," depending on what else is happening in the economy.

9. RESULTS: FISCAL IMPACTS

This chapter provides general estimates of fiscal cost-revenue impacts for two levels of local government – the State and the City and County of Honolulu. The central question for such analyses is simply whether build-out under either TOD Alternative is likely to generate more revenues than costs for each level of government, compared to the cost-revenue balance for build-out under existing HCDA Rules. The answers to this question are subject to ***important caveats discussed in the following Section 9.2***.

However, the chapter first begins with a qualitative discussion about evidence for overall governmental cost savings for concentrated development patterns such as TOD versus dispersed development patterns, and then sets forth quantitative estimates of the impacts of the proposed Alternatives. The quantitative analyses are properly done at the *islandwide* level, and so flow primarily from the results of the previous two chapters rather than the earlier ones on Kaka'ako-specific impacts.

9.1 General Principles of Concentrated Versus Dispersed Development

Among other things, the TOD Alternatives will result in a *population shift* of some 12,800 full-time residents (for Alternative A, or 9,100 for Alternative B) into the Kaka'ako area who would otherwise be living "somewhere else" on O'ahu as of 2035. Though it may reasonably be assumed that many of these people would choose to live in other high-density areas, likely even in other TOD developments around future HART stations, there is no way to know exactly where they would choose to live under the Future Baseline Condition. They would almost certainly not be in a single identifiable alternative location, but would be dispersed to various locations throughout the island. Therefore, it is impossible to quantify government costs – especially facility development costs – associated with accommodating this relatively small population[45] under the Future Baseline Condition.

However, each of the TOD Alternatives are consistent with State and City policies to concentrate much of the island's future growth in Kaka'ako or similar higher-density locations, particularly HART-related TOD. Those policies reflect general principles of reduced governmental costs and other economic benefits.

For governments, economic benefits associated with TOD-style concentrated development patterns include:

- Savings on city infrastructure and public facilities operations and maintenance costs;
- Increases in municipal revenues;
- Increased property values;
- Lower transportation costs;
- Promotion of local economic development; and
- Savings on health care.

[45] The Hawai'i State DBEDT Long-Range Forecasts a 2035 O'ahu population of 1,071,221. The population shift would thus involve roughly 1% of the island's total number of full-time residents.

Recent studies[46] have shown that "growth focused in existing urban areas takes advantage of existing infrastructure and capitalizes on the efficiencies of providing service to higher concentrations of jobs and housing."[47] The studies indicate that more dispersed development require more lengthy roads, greater sewer and water systems infrastructure, and generally incur larger operations and maintenance costs than compact development. TOD is able to maximize infrastructure capacity, and keep overall costs down.

Public facilities and services are also more efficient in TOD, where development is more compact by promoting quicker response times for such services as police and fire on a smaller footprint. School grounds in TOD are also more compact,[48] thus decreasing overall operating and maintenance costs. Denser locations (such as TOD), and close proximity to major transit systems are also reported as supporting higher property values. Because of this, compact development typically generates higher local revenues than more dispersed development.

Compact development can help generate revenue for the private sector as well. It is reported that, "Projects near transit are viewed as having the potential to achieve faster absorption rates, higher occupancy rates, and in some cases higher sales prices or rents".[49] Because TOD supports greater proximity to transit, work, shopping and recreational uses, TOD residents also enjoy lower transportation costs, which results in greater overall affordability for households. Additionally, TOD projects have the potential to generate enhanced economic activity related to new construction, neighborhood urban revitalization; thus promoting local economic development. Finally, TOD can help reduce the cost of medical care and impact on local medical facilities, by promoting healthier lifestyles, encouraging walking and biking, and allowing residents enjoy the health benefits associated with reduced energy consumption, which reduce greenhouse gas emissions and air pollution.

9.2 Methods and Caveats for Quantitative Analysis

It is important to reiterate that results of this analysis focus on the net new *islandwide* components largely common to each TOD Alternative – i.e., three new hotels and an increment in the part-time resident population – plus construction of public facilities and infrastructure (whether in Kaka'ako or elsewhere on island) assumed to occur only due to the TOD Alternatives. There will be many public expenditures required, and revenues

raised, in Kaka'ako as a result of the TOD Alternatives that will also be generated no matter where on O'ahu that new residential and commercial demand is accommodated.

Because the methods underlying this analysis yield results that appear very precise, it is also useful to remind the reader that all the input to this analysis stem from assumed "scenarios" of possible ways that Kaka'ako might build out under existing Rules (Future Baseline Condition) and or proposed TOD Alternatives (A or B). Like every other analysis in this report, the following fiscal cost-revenue calculations are actually *illustrative and indicative* of potential outcomes – not calculations of specific known proposals that developers/landowners have stated firm intentions to carry out.

Furthermore, the ***islandwide inputs to the analysis are very similar, meaning the results will be very similar.*** This chapter will present separate results for each Alternative, but will also point out their practical equivalence.

Beyond this general sense of testing the changes in two *very* hypothetical long-term realities, this cost-revenue analysis is constrained by key uncertainties related both to assumed costs and assumed revenues.

Government Cost Uncertainties: Chapter 7, the analysis of "Public Services and Facilities," pointed out several concerns about costing future facility construction and operations for Kaka'ako and urban Honolulu in general –

- While no new publicly-funded Kaka'ako park or recreational facilities are proposed as of this writing, the additional population expected under *either* scenario will greatly impact existing/nearby facilities. HCDA is planning a study of likely recreational needs and solutions that *might* result in more taxpayer-funded facilities. Whether such taxpayer-supported facilities will actually be developed, and whether or to what extent costs would be higher due to either of the TOD Alternatives, remains an Unresolved Issue as of this writing. It is probably the most critical of the issues noted in this short series of bullet points.

- Similarly, Hawai'i in general faces challenges to provision of enough public health facilities – private or public – as the population grows. While either one of the TOD Alternatives is highly unlikely to determine the nature of the final response to these challenges, it should be remembered that some additional public expenditures are likely to be needed under any of the scenarios, including the Future Baseline.

Furthermore, as discussed in the relevant methodology Section 2.8, government costs and revenues – for both services and for capital expenditures – generally balance out for residential population increases, and so this analysis estimates service costs only for transient populations and includes no averaged capital costs. However, as a strongly conservative step, islandwide service and facility costs (particularly DOE facility costs) are included if they were attributed by the agencies to this project. It is not clear that this is appropriate, since it could be viewed as double-counting, but these costs *will* be included, albeit subject to comment about their overall effect on results.

Government Revenue Uncertainties: All revenues cited in this analysis come from standard tax sources typically associated with the sorts of costs that have been listed. However, the HCDA is an atypical agency – it is a *development authority* with the powers to set or negotiate impact fees. That means it is possible that some currently unknown amount of revenues will come not from overall taxpayers, but initially from developers and ultimately from residential or commercial purchasers/lessees.

HCDA is exploring various "value capture" mechanisms by which it might gain additional revenues from landowners, developers, etc. Depending on whether and how such mechanisms are employed, the illustrative fiscal cost-revenue analysis in this chapter could turn out very differently.

Beyond the foregoing caveats and uncertainties … the full methodology, including explanation of assumed multipliers, is to be found in the foregoing Chapter 2, Section 2.8. As noted there, analysis for each level of government must be divided into:

1. The Construction phase, which for this analysis involves the *cumulative* effects of all construction over time; and

2. The Operational phase, which is properly assessed at a representative point-in-time *annual* basis.

In a standard fiscal cost-revenue analysis, results of both phases would be presented together in a single table for each TOD Alternative by year, with cumulative figures indicating points in time when any negative balance for Construction might be eventually offset by potential positive balances for Operations. That is not possible for this sort of hypothetical analysis with unclear timeframes, but the textual interpretation of the tables will note when and if such offsetting results are found.

As with other islandwide analyses, this analysis reflects inputs that are already "impacts" (i.e., differences between each of the TOD Alternatives and the Future Baseline Condition), and then calculates results from those. This generates results identical to those that would flow from the more cumbersome procedure of separately calculating Future Baseline Condition and TOD Alternative results, and then subtracting.

9.3 Construction Phase

9.3.1 State Results

The upper parts of Table 9.1 and Table 9.2 indicate that construction elements, in and of themselves, would result in about a $2.3 million net revenue *loss* for the State for TOD Alternative B and a larger $6.5 loss for Alternative A. The private-sector portions of the equation (hotels and part-time residential population) generate overwhelmingly

positive returns. However, these are substantially though not entirely offset by the very conservative inclusion of DOE public school costs for land acquisition and construction.

In an analysis of this nature, these apparent net losses are actually relatively small and fairly similarly. Perhaps more importantly, ***they would be offset by considerably larger annual Operational phase positive balances*** (see following Section 9.4.1) at build-out. As will be seen, just one year's net Operational positive balance for State government would wipe away the calculated loss from the Construction phase under either TOD Alternative A or B.

.

9.3.2 County Results

The lower parts of Table 9.1 and Table 9.2 show modest positive balances of a little over $2 million each for the City and County of Honolulu for TOD Alternatives B and A, respectively. This is in part because of the assumption that County revenues are limited to a modest share of the General Excise Tax (GET).

It also reflects the very small County costs *or* revenues that can be directly associated with this very marginal addition to a much larger directed growth strategy. In the "bigger picture," as per studies reviewed in the foregoing Section 9.1, concentrated development on average is more cost-effective for municipal governments than is dispersed development.

.

Note: Figures reflect differences ("impact") – i.e., TOD Alternative A minus Future Baseline Condition.

9.4 Operational Phase

9.4.1 State Results

The upper parts of Table 9.3 and Table 9.4 indicate the State would receive considerably more revenues than costs (about $14.1 million each year for TOD Alternative B and a roughly equal $14.8 million for Alternative A) due to operations of the net new islandwide components.

This is because service costs associated with new transient hotel and part-time resident populations – as well as service costs for residents conservatively assumed to be on-island only because of these economic activities – are greatly outweighed by State tax revenues.

9.4.2 County Results

The lower parts of Table 9.3 and Table 9.4 have two "bottom lines." As explained in Section 2.8.2, county government portions of the Transient Accommodations Tax (TAT, the "hotel room tax") have recently been capped by the State Legislature, such that additions to the lodging inventory under present law would not add to county coffers on any island. But for the long range, it seems reasonable to project the results if the cap is removed and additional TAT money again flows to counties under the previous formula.

If municipal revenues are limited to the GET and increased property tax values for the three hotel sites, the differences between the City and County's revenues and costs – a positive $0.08 million and negative $0.41 million for Alternative B – are essentially zero, considering all the uncertainties in this analysis.

If the TAT is restored, the analysis suggests the TOD Alternative B would generate a small positive annual balance for the County of about $1.2 million per year, and an essentially similar $0.7 million for Alternative B. Even these greater positive figures are quite small in light of the uncertainties underlying this analysis, although they are achieved in the face of various conservative assumptions. The real conclusion to be drawn from the County portions of Table 9.3 and Table 9.4 is that the project is unlikely to have any real perceptible impact at all on annual County operating budgets.

Table 9.3: State and County Fiscal Cost-Revenue Impacts – Operational Phase – TOD Alternative B

Costs/Revenues Flowing from Change from Future Baseline to TOD Alternative B – Stabilized Operations (Annual)	Full-Service Hotel	Business Hotel	Condo-Hotel	Change in State Operational Spending[1]	Change in County Operational Spending[1]	Change in Part-Time Residents	TOTAL

Urban Design Aesthetics Methodology

METHODOLOGY APPENDIX

The TOD Overlay Land Use Alternative was developed by the Hawaii Community Development Authority using a blend of methods including 3D modeling programs (Revit, Sketch-up and Google Earth) to test a potential forfull build-out of the area. This model is used to estimate redevelopment proposals, and frequency and spacing of towers meeting the criteria in the design standards in the Mauka Area Rules Chapter 217-15 and the table following.

Future Baseline Condition

The Future Baseline Condition also includes the entitled Master Plan areas; Kamehameha Schools, and Ward Centers. No changes were assumed to these areas.

TOD Overlay Plan Alternative Assumptions

The TOD Alternatives were developed using 3D modeling programs (Revit, Sketch-up and Google Earth) to test a potential build-out of the area, including an exploration of selected sites eligible for redevelopment under proposed either TOD Alternative. This model is used to estimate the frequency and spacing of towers meeting the criteria proposed by the design standards as listed in the table below. The model also provided assumptions for program, capacity and parking assumptions for the Mauka area. Assumptions used for the placement and scale of potential TOD developments are listed following:

In Mauka:

- Site eligibility: all TOD eligible under developed sites will redevelop in the future, unless otherwise constrained by an existing major project (such as an existing tower, condominium), a historic property, institutional land holder, park or open space, or currently engaged with a development permit.
- Where individual parcels with separate ownership are contiguous and can be assembled to make a lot size of 40,000 SF or greater, a developer or property owner will do so to build the maximum gross building area allowable with reasonable allowances for required parking, access, floor plate and height restrictions. Sites less than 40,000 SF will generally develop to their maximum using underlying zoning.
- High Rise developments are constrained by guidelines for height allowances, lot criteria, placement and spacing as noted..
- On adopted Master Plan Areas (Kamehameha Schools) and (Ward Centers Master Plan) general assumptions were made on allocation of new potential residential square footage applicable to the relevant land area. Additional square footage in these locations are assumed to be **residential**, and would be allocated primarily in the addition of taller heights in planned towers, or the application of additional towers on a compatible site.
- New public open space, although a likely incentive for accessing maximum FAR is generally not shown except on Blaisdell Center (this is a publically owned site) and the HECO property (this is a large consolidated property). On smaller parcels, the open space amount and location would be unknown and speculative. Assumptions that open space would be provided at a minimum comparable rate with the Mauka Area Rules, with additional public open space with greater intensity of use.

In Makai

- The project land use alternative took into account the best available information on potential build-out concepts of existing property owners in Makai, meeting the goals and objectives of the Kaka`ako Makai Conceptual Master Plan. For purposes of Analysis the Makai land area is generally shown with dashed lines to show the extent of current height limitations.

Standard	TOD A	TOD B	Mauka Area Plan
Lot Size and Dimension	A minimum lot size of 40,000 SF Heights greater than 420' and up to 550' require a minimum lot size of 90,000 SF (one tower of per development site).	40,000 Sq Ft assumed	All high-rise buildings must have a minimum lot size of 20,000 SF. Maximum lot width is 300'
Street Front Element	75' max height street fronts is proposed for Commercial Boulevards and Avenues. 65' max height is preferred for District Streets (Residential Streets, Local Streets, and internal connectors). 50' setbacks are required tower floor plates above the Street Element on identified Mauka-Makai view corridor streets.	75' max height street fronts is proposed for Commercial Boulevards and Avenues. 65' max height is preferred for District Streets (Residential Streets, Local Streets, and internal connectors). 50' setbacks are required tower floor plates above the Street Element on identified Mauka-Makai view corridor streets.	Street Front Element is currently required at 65'. Variances allowed under both KS and Ward Master Plans. 50' setbacks are required tower floor plates above the Street Element on identified Mauka-Makai view corridor streets.
Building Placement and tower siting	No change is proposed to Mauka build-to lines. Tower siting is flexible. Towers are preferred to be staggered on a development site to preserve internal / external views.	No change is proposed to Mauka build-to lines. Tower siting is flexible. Towers are preferred to be staggered on a development site to preserve internal / external views.	Build-to lines as defined in the Mauka Area Regulating Plan define building placement. **At least 65% of the tower must be flush with the street except in the case of a view corridor street.**
Tower Separation	Maintains requirement as identified in the Mauka Area Rules	Maintains requirement as identified in the Mauka Area Rules	80' is required as a separation between towers (i.e. building above 100' in height.)
Building Types **Tower / Floor Plate controls**	Untethers floor plate from lot size and controls floor plate by building type. Maintain maximum length of 210' between the two farthest points of the tower floor plate. *High rise Commercial/Office*; 28,000 SF/ 240' maximum	Untethers floor plate from lot size and controls floor plate by building type. 1 PURPOSE

The purpose of this study was to provide an updated water master plan for the Hawai‘i Community Development Authority (HCDA) Kaka‘ako Community Development District (KCDD) – Mauka Area. The analysis reflected development projects currently or soon to be under construction, developments and infrastructure upgrades proposed by the Howard Hughes Group (HHG) for its properties within the district, and increased densities proposed in the Transit Oriented Development (TOD) Overlay for the KCDD Mauka Area. Infrastructure requirements determined in previous utility analyses did not include the proposed density increases and infrastructure improvements. These previous utility analyses were presented in the *Mauka Area Infrastructure Plan*[1], which was prepared in conjunction with the *KCDD Final Supplemental Environmental Impact Statement – Mauka Area Plan*[2].

Recommendations were made to upgrade the water infrastructure system to meet the demands of the projected development scenarios. The master plan update will be used by the Honolulu Board of Water Supply (BWS) as a guide for evaluating infrastructure needs for future developments within the KCDD Mauka Area.

2 BACKGROUND

The KCDD study area is approximately 503 acres, bounded by South King Street, Pi‘ikoi Street, Ala Moana Boulevard, and Punchbowl Street, as shown in Figure 1. HCDA is considering rule changes for the KCDD to incorporate TOD. Rule changes would permit greater development densities than currently allowed under the Mauka Area rules. The water master plan maintained by BWS does not reflect the ongoing developments or proposed densities that would be allowed in the Mauka Area rule changes. The BWS master plan for the KCDD Mauka Area was last updated in 2009. This current study analyzed the existing water infrastructure system and commented on whether the existing system could sustain an increase in development density.

The analysis considered five scenarios: the existing condition, a Future Baseline condition, two TOD Overlay alternatives (TOD Alternative A and TOD Alternative B), and the 690 Pohukaina Street Project. Where appropriate, projects currently approved for development were incorporated into each scenario.

A capacity study was prepared for each scenario, identifying the total number of residential units and areas defined by non-residential uses (e.g., office space, commercial space, etc.) in accordance with existing or proposed development rules. Generally, the capacity study was started by determining the maximum developable floor area available to a project based on the parcel area and underlying zoning rules. This area was reduced to account for open space, circulation, and parking requirements, and then adjusted further to account for building setback and height limit requirements. The developable area was then proportioned between residential and commercial

[1] M&E Pacific, *Kakaako Community Development District, Mauka Area Infrastructure Plan* (Honolulu: March 2009).
[2] EDAW, Inc., *Kakaako Community Development District, Final Supplemental Environmental Impact Statement, Mauka Area Plan* (Honolulu: May 2009).

uses. A 4:1 ratio of residential area to commercial area was applied; however, the actual ratio will vary depending on market demand and the developer's requirements. The total number of residential units was then determined by dividing the total residential area by average unit floor areas for different types of units (e.g., luxury, moderate, or workforce units). The unit floor areas ranged from 750 square feet for workforce units to 2,000 square feet for luxury units.

The capacity study only suggested a plausible development scenario. The HCDA Rules allow for a great degree of flexibility in development. Blocks may be developed as a single project or as multiple smaller parcels, and proposed uses may vary widely. Furthermore, development within the KCDD occurs on an opt-in basis. A definitive development schedule or plan for the KCDD is unavailable; therefore, the master plan may not reflect the developments that are ultimately implemented. The development scenarios are summarized below.

- The existing condition was defined as the current land uses for each tax map key parcel and included redevelopment projects currently under construction. Uses and densities were derived from real property records of the individual tax map parcels within the study area.
- The Future Baseline condition represented full build-out in accordance with the current Mauka Area rules. Redevelopment was evaluated by large city blocks that combine several adjacent TMK parcels generally bound by the existing street grid.
- The 690 Pohukaina Street Project is a high-rise condominium project that was incorporated into TOD Alternative A and TOD Alternative B. The project was evaluated separately from the TOD alternatives since completion of the project is anticipated prior to full build-out of the TOD alternatives. The existing condition model was modified to incorporate the project.
- TOD Alternative A represented the full build-out of the KCDD with an increase in densities above what is currently allowed in the Mauka Area rules.
- TOD Alternative B proposed densities similar to the TOD Alternative A, but with a 400-foot building height limit.

For the purposes of the water master plan update, baseline demands for specific properties that are not likely to be redeveloped were applied in all development scenarios. For example, current demands from existing high-rise condominiums, government agency facilities, open space areas such as parks and cemeteries, and projects near or under construction were assumed to remain for each scenario.

Of the three future full build-out scenarios, TOD Alternative A proposes the highest densities and would result in higher water consumption than TOD Alternative B and the Future Baseline condition. Consequently, only the impacts of TOD Alternative A development on the water system were analyzed. The infrastructure improvements proposed for TOD Alternative A would also address the impacts of TOD Alternative B and Future Baseline development on the water infrastructure.

3 ANALYSIS

This water master plan update was prepared in accordance with *Water System Standards* (2002) and additional requirements from BWS that are specific to the KCDD. BWS indicated sufficient water resources are available to serve the KCDD; however, the capacity of the water distribution system within the KCDD needed to be evaluated.

The water system within the KCDD is an interconnected grid with multiple sources and multiple points of inflow and outflow. For the purposes of this update, multiple sources are assigned at water mains equal to and greater than 12" in diameter located at the perimeter of the study area with a starting pressure equal to average system pressures computed by the BWS.

3.1 DOMESTIC WATER CONSUMPTION

The average daily demands for uses published in Table 100-18, Domestic Consumption Guidelines, of the Water System Standards were evaluated for this master plan. At the request of BWS, the average daily consumption rates for multifamily residential and commercial uses were re-evaluated using recent historical water meter billing records and real property records for representative properties within the KCDD. The consumption rates were then aggregated by land use type and averaged to determine revised average daily demand rates (see Table 1). Derivation of the revised demand rates was limited to land use types that are prevalent within the KCDD, including multifamily residential, civic/office, and commercial/restaurant. Average daily demands from *Water System Standards* were used to determine average demands for other land use types.

Table 1: KCDD Water Consumption Rates

Land Use	Standard Average Daily Consumption Rate	Proposed Average Daily Consumption Rate
Single Family Residential	500 gallons / unit	500 gallons / unit
Multifamily Residential	400 gallons / unit	200 gallons / unit
Civic / Office	n/a	120 gallons / 1,000 square feet (sf)
Commercial/Restaurant	69 gallons / 1000 sf (3,000 gallons / acre)	300 gallons / 1000 sf (13,100 gallons / acre)
General/Light Industry	92 gallons / 1000 sf (4,000 gallons / acre)	92 gallons / 1000 sf (4,000 gallons / acre)
School	60 gallons / student	60 gallons / student

The proposed average daily consumption rates listed in Table 1 were applied to all scenarios to determine the average daily consumption. Maximum daily and peak hour demand factors from Table 100-20 in *Water System Standards* were then applied to the average daily demands to determine the respective high-volume demands. Domestic water consumption demands for the planned HHG developments were provided by Wilson Okamoto Corporation. See Tables A through D at the end of this report for the domestic water consumption rates utilized in the modeling.

Domestic consumption rates for adjacent properties were generally aggregated by neighborhood blocks and the domestic demand for each block was applied to a single junction within the KCDD water system model (see Figure 1).

3.2 WATER SYSTEM REQUIREMENTS

Analysis of the water distribution system was based on planning criteria from *Water System Standards*. The following criteria were utilized for all scenarios:

- Pipelines shall be sized to accommodate maximum daily flow plus fire flow with a minimum residual pressure of 20 pounds per square inch (psi) at fire hydrants.
- Pipelines shall be sized to accommodate peak hour flow with a minimum residual pressure of 40 psi.
- The maximum velocity in distribution mains without fire flow shall be 6 feet per second.

In addition to planning criteria from *Water System Standards*, BWS requires fire flow for the entire KCDD to be equal to 4,000 gallons per minute (gpm). KCDD is envisioned to be a densely developed area similar to Waikīkī or downtown Honolulu. This additional requirement was incorporated into the analyses of each scenario.

3.3 HYDRAULIC ANALYSIS

The KCDD water system was analyzed using the water distribution modeling software WaterCAD. The base water system model provided by BWS, which was limited to the KCDD area, was extracted from BWS' overall system model. The water system within the KCDD is part of a larger, interconnected grid that draws water from multiple sources to deliver water to a specific location. Any water system demand applied to an area outside of the KCDD has the potential to impact the water system within the study area.

Recent system improvements and planned improvements to be constructed by BWS or by HHG were also incorporated into the model as appropriate. The following improvements were incorporated into the model and are shown in Figure 2:

- Ward Avenue – Replace an existing 12-inch diameter main with a new 12-inch diameter main and a new 8-inch diameter main from Kapiʻolani Boulevard to Kīnaʻu Street. This improvement was recently completed and was added to all scenarios.
- Ala Moana Boulevard – Replace an existing 12-inch diameter main with a new 24-inch diameter main from Aloha Tower Drive to Kalākaua Avenue. This BWS improvement is planned for construction and was only added to the TOD Alternative A scenario.
- Cooke Street – Replace an existing 12-inch diameter main with a new 20-inch diameter main from Ala Moana Boulevard to Pohukaina Street. This BWS improvement is planned for construction and was only added to the TOD Alternative A scenario.
- Queen Street – Replace an existing 6-inch diameter main with a new 12-inch diameter main from Cooke Street to an existing 12-inch diameter main located between Cummings Street and Kamakee Street. This HHG improvement is planned for construction and was only added to the TOD Alternative A scenario.

To approximate conditions at the boundary of the KCDD water model, multiple incoming sources and outgoing flows were assigned to water mains equal to and greater than 12 inches in diameter located at the perimeter of the study area. Water draws and source pressures at the boundary of the study area were based on average values provided by BWS. No adjustments were made to the average demands and pressures to account for population growth or specific peak demand scenarios.

The existing water distribution system southwest of Ala Moana Boulevard from Punchbowl Street to Ward Avenue is isolated from the rest of the grid by the water system within the KCDD. Consequently, an increase in water consumption from developments within the KCDD could potentially impact this isolated water system. The water system in this area was analyzed in accordance with *Water System Standards* planning criteria for each scenario. Demands for this area were included in the hydraulic model provided by BWS and were held constant for each development scenario and specific peak demand scenario. Under all scenarios, no significant impacts are anticipated to the existing water system in this isolated area due to the proposed increase in densities within the KCDD.

Fire flow demands were applied to selected junctions throughout the KCDD study area. The fire flow junctions were distributed across the study area to obtain representative results for the entire KCDD water system.

3.4 RESULTS

An overall reduction in domestic water consumption of approximately 35 percent was realized by using the proposed average daily consumption rates rather than the current *Water System Standards* rates. The proposed development scenarios are heavily weighted toward multifamily residential units, which largely contributed to the reduction in overall consumption because the proposed average daily consumption rate is half of the *Water System Standards* rate for multifamily residential units.

The existing water system within the KCDD is adequate to meet peak hour domestic demands for all scenarios; however, the existing system is inadequate to meet the fire flow requirement for all scenarios. Specifically, fire hydrants along existing 6-inch diameter water mains will not have adequate residual pressure when operating at 4,000 gpm (see Figures 3 through 5). The model also indicates velocities in some existing 6-inch and 8-inch diameter water mains approaching 30 feet per second and 20 feet per second, respectively, under fire flow conditions. These velocities are well above the general engineering practice maximum value of 10 feet per second.

3.5 MITIGATION MEASURES

The following improvements are recommended for all scenarios:

- Replace approximately 37,580 lineal feet of existing 6-inch and 8-inch diameter mains with new 12-inch diameter mains throughout the KCDD.

The locations of the proposed 12-inch diameter replacement mains are shown in Figure 6. Under fire flow, velocities through the 12-inch diameter replacement mains within the grid system are estimated to drop below 10 feet per second. The larger replacement mains will also provide adequate residual pressures for fire hydrants in operation. The same improvements will satisfy fire flow requirements and pipe velocities for the existing, 690 Pohukaina Street Project, Future Baseline, and TOD Alternative B scenarios.

Water system upgrades will be implemented in phases corresponding to the growth in development density. Improvements may be implemented by the HCDA on an incremental basis prioritizing aging infrastructure or may be implemented by developers to support their projects.

4 OPINIONS OF PROBABLE COST

Opinions of probable costs are estimated for the proposed mitigation measures. A lineal foot unit cost for water line installation is derived from recent similar sewer line construction projects. The total cost includes design fees equal to 10% of the probable construction cost and a 25% contingency.

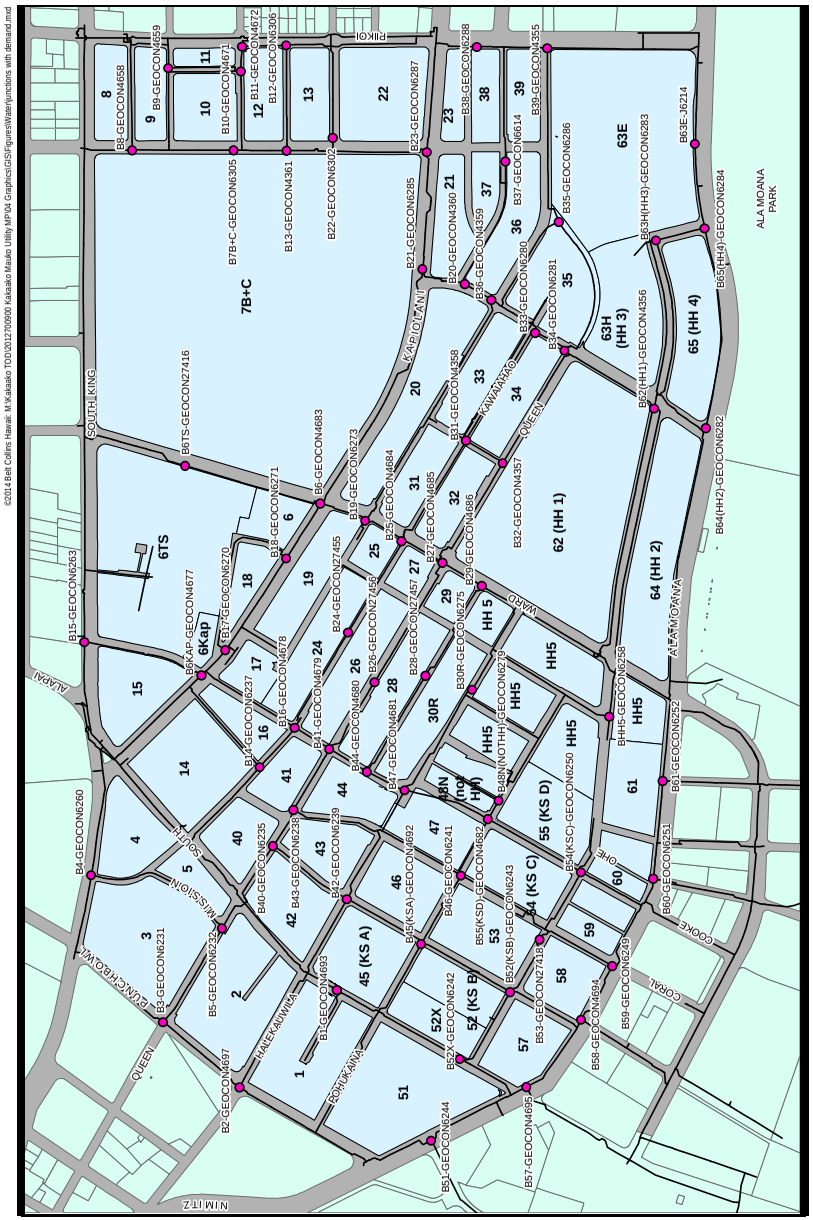
Table E: Opinion of Probable Construction Costs

Mitigation Measure	Unit Cost	Future Baseline	TOD Alternative A
Replace approximately 37,580 lineal feet of existing 6-inch and 8-inch diameter mains with new 12-inch diameter mains throughout the KCDD.	$1,300 / lf	$49,100,000	$49,100,000

The cost of the system upgrades will be incurred over time as the water system is upgraded in phases.

5 SUMMARY AND RECOMMENDATIONS

The existing KCDD Mauka Area water system as modified by planned BWS and HHG system improvements is capable of meeting peak hour domestic consumption demand requirements; however, the existing system is unable to meet fire flow requirements. Approximately 37,580 lineal feet of existing 6-inch and 8-inch diameter mains will need to be replaced with new 12-inch diameter mains to accommodate the 4,000-gpm fire flow requirement and maintain pipe velocities within an acceptable range. These improvements are recommended for the existing, 690 Pohukaina Street Project, Future Baseline, TOD Alternative A, and TOD Alternative B scenarios. The 690 Pohukaina Street Project will result in a relatively small increase in overall water consumption that is not anticipated to negatively impact the existing water distribution system.



The recommendations prepared for this master plan update are based on a steady-state analysis of the KCDD Mauka Area water system model provided by BWS. The KCDD water model was extracted from a larger, interconnected grid system that draws water from multiple sources to deliver water to a specific location. Average pressures and outgoing flows provided by BWS were used across all scenarios to approximate boundary conditions for the KCDD water system. Any changes to the water system outside of the KCDD have the potential to impact the water system within the study area.

Kaka`ako Sewer Master Plan Update

SEWER MASTER PLAN UPDATE

HCDA KAKA'AKO MAUKA DISTRICT

Kaka'ako, O'ahu, Hawai'i

December 2014

Prepared for:
Lee Sichter LLC
45024-1 Malulani Street
Kāne'ohe, Hawai'i 96744
and
The Hawai'i Community Development Authority

Prepared by:
BELT COLLINS HAWAII LLC
2153 North King Street, Suite 200
Honolulu, Hawai'i 96819

2012.70.0900

1 PURPOSE

The purpose of this study is to provide an updated sewer master plan for the Hawai'i Community Development Authority (HCDA) Kaka'ako Community Development District (KCDD) – Mauka Area. The analysis reflects development projects currently or soon to be under construction, developments and infrastructure upgrades proposed by the Howard Hughes Group (HHG) for their properties within the district, and the increased densities proposed in the Transit Oriented Development (TOD) overlay for the KCDD Mauka area. The infrastructure requirements associated with the current developments and infrastructure improvements were not available at the time the previous utility analyses presented in the *Mauka Area Infrastructure Plan*[1] prepared in conjunction with the *KCDD Final Supplemental Environmental Impact Statement – Mauka Area Plan*[2] was prepared.

Recommendations for system improvements are made to upgrade the infrastructure system to meet the demands of the projected development scenarios. The master plan will be used by the City and County of Honolulu (City) as a guide for evaluating infrastructure needs for future developments in the KCDD Mauka Area.

2 BACKGROUND

HCDA is considering rule changes for the KCDD to incorporate transit oriented development. Rule changes would permit greater development densities than currently allowed under the Mauka Area rules. The sewer master plan maintained by City does not reflect the on-going developments or proposed densities as allowed in the Mauka Area rules. The City master plan for the KCDD Mauka Area was last updated in 2009. This study will model the existing sewer infrastructure systems and comment on whether the existing systems can sustain an increase in development density.

The study area is approximately 503 acres, bound by South King Street, Pi'ikoi Street, Ala Moana Boulevard, and Punchbowl Street. The analysis considers four scenarios: the existing condition, a Future Baseline Condition, the Proposed TOD Alternative A, and the 690 Pohukaina Street Project. Where appropriate, projects currently approved for development are incorporated into each scenario.

- The existing condition is defined as the current land uses for each tax map key parcel and include redevelopment projects that have an approved sewer connection application or that are currently under construction. Uses and densities were derived from real property records of the individual tax map parcels within the study area.
- The Future Baseline Condition represents full build out in accordance with the current Mauka Area rules. Redevelopment is evaluated by large city blocks, combining several

[1] M&E Pacific, *Kakaako Community Development District, Mauka Area Infrastructure Plan* (Honolulu: March 2009).
[2] EDAW, Inc., *Kakaako Community Development District, Final Supplemental Environmental Impact Statement, Mauka Area Plan* (Honolulu, May 2009).

adjacent TMK parcels generally bound by the existing street grid. A capacity study[3] detailing the number of residential units and floor areas for non-domestic uses was prepared, presenting a plausible development plan in conformance with the current Mauka Area rules.

- The TOD Alternative A represents the full build out of the KCDD utilizing an increase in densities over and above what is currently allowed in the Mauka Area rules. A redevelopment plan was prepared using the same methodology as the Future Baseline Condition with the proposed TOD Alternative A densities.
- The TOD Alternative B proposes densities similar to the TOD Alternative A, however, with a 400-ft building height cap imposed. The resulting densities for Alternative B are approximately 10% less than Alternative A. Given the marginal difference in densities, the master plan analysis considers only the greater densities proposed under TOD Alternative A.
- The 690 Pohukaina Street Project is a high-rise condominium project that is incorporated into TOD Alternatives A and B. The project is evaluated as being constructed prior to full build out of the TOD Alternatives. The existing condition model was modified to incorporate the project.

For the purposes of the infrastructure master plan update, infrastructure demands for specific blocks in the Future Baseline and TOD Alternative A scenarios were adjusted to reflect properties that are not likely to be redeveloped. For example, high-rise condominiums, government agency facilities, open space areas such as parks and cemeteries, and projects near or under construction are assumed to remain under both scenarios. See Figure 1 in the appendix.

3 ANALYSIS

This sewer master plan update is generally prepared in accordance with Chapter 20 of the Design Standards of the Wastewater Department (Design Standards), Volume 1, July 1993. The hydraulic analysis was performed using the EPA Storm Water Management Model (SWMM) version 5 as implemented in the Autodesk Storm and Sanitary Analysis 2014 application.

3.1 POPULATION

The land use categories and corresponding capita rate are utilized for the existing condition:

Table 1: Population Rates

Use	Unit Capita	Unit	Average daily flow rate (gpcd)
SF Residential	4 residents	Dwelling	80
MF Residential	2.8 residents	Dwelling	80
Civic / Office	300 employees	Acre	25
Retail	140 employees	Acre	25
General/Light Industry	100 employees	Acre	25
Parking Structure	1 employee	Each	25
School	1 student	Per 80 sf	25
Restaurant	1 cover	Per 25 sf	5 gal/cover @ 6 services per day
Cinema	Metered water consumption rates used in lieu of population estimates based on patronage.		

See Tables 2, 3, and 4 in the appendix.

3.2 FLOW DETERMINATION

The determination of total wastewater flow generally conforms to the Design Standards. The design wastewater flows and dry weather infiltration/inflow are determined in accordance with the Design Standards. All sewers are assumed to be below the ground water table. A single flow factor is determined for each scenario, based on the total equivalent population for that scenario. Wet weather inflow and infiltration (WWI/I) is not computed in accordance with the Design Standards, rather, is based on the 5 year 24 hour values provided by the City[4]. The design and WWI/I flow values are assigned to the corresponding manholes. See Figures 1B, 1C, Table 5, and Table 6 in the appendix.

The off-site sewage flow rates are adjusted to reflect population growth for the Future Baseline and TOD Alternative A scenarios. Off-site sewer service basins which drain to the KCDD system were determined for each boundary SMH where offsite flows are applied in the model. The model assumes the net change in off-site sewer generation is equivalent to the average population growth within the off-site sewer basin.

Population growth rates are derived from projections for Development Plan Areas and subareas developed by the City and County of Honolulu.[5] Growth rates are computed by comparing 2010 and 2035 projections for each area. Local rates of change vary from a decrease of 1.5% in Wai'alae-Kahala to an increase of 94.1% over 2010 in the Ala Moana-Kaka'ako area.

[3] Note the capacity study only suggests a possible development scenario. The HCDA Rules allow for a great degree of flexibility in development. Blocks may be developed as a single project, or as multiple smaller parcels and proposed uses may vary widely.

[4] Updated City sewer models indicate the 5 year 24hr inflow and infiltration values are much higher than the what is computed using the Design Standards.

[5] Department of Planning and Permitting projections posted at http://www.honoluludpp.org/Portals/0/pdfs/planning/demographics2/Projections/2000-2035byDPSA.pdf. The projections were made in 2009, and based on the State's 2035 Series of State and County population projections. More recent projections are available for the State and County, but not for subareas.

Table 7: Offsite Sewer Flows

Boundary SMH	Existing Design Maximum Flow (mgd)	Average Year 2035 Population Growth Factor	Future / TOD Alternative A Design Maximum Flow (mgd)	Wet Weather I/I 5 yr 24 hr (mgd)

Wet weather I/I values as derived from City dataset.

3.3 HYDRAULIC ANALYSIS

The sewer infrastructure system hydraulic network modeling is performed using hydrodynamic routing methods. A static hydraulic model is inappropriate for this analysis as several sections of the existing sewers in Kaka'ako are at adverse slopes[6]. Per discussions with the City and County of Honolulu Department of Design and Construction (DDC), the following modeling parameters area utilized to maintain consistency with the DDC's models:

- Mannings n = 0.013 for all reaches
- No entrance or exit losses are applied to manhole junctions

[6] Sewer mains with adverse slopes slope uphill. This condition generally occurs where sags in the sewer mains have developed. The computations used to compute pipe flow in a static model would yield erroneous results when applied to adversely sloped sections.

The sewer network is based on GIS data obtained from the City. Apparent discrepancies in the GIS data were confirmed or corrected in consultation with the City. Modifications to the sewer networks for the Future Baseline and TOD Alternative A were made to incorporate the proposed improvements planned by the HHG within the study area. HHG is proposing to:

- Install a 24" relief sewer in Ward Avenue between Ilaniwai and Auahi Streets
- Reroute the 48" trunk sewer from under the Ross Dress for Less and Sports Authority stores into Ward Avenue
- Replace the 6" sewers in Pohukaina Street between Koula and Ward Avenue with 12" sewers
- Install a 36" sewer in Auahi Street between Kamakee Street and Ward Avenue
- Replace the 8" sewer in Auahi Street between Kamakee Street and Queen Lane with a 12" sewer.

See Figure 2 in the appendix.

3.4 OFF-SITE RELIEF SEWER PROJECTS

The City is studying several relief sewer projects outside the KCDD that will provide increased sewer capacity to the Mauka Area. The details of these relief sewer projects, including time schedules, are currently being evaluated internally at the City and have not been released to the public at this time. The City has indicated the relief sewer projects will be designed to accommodate TOD developments outside of the KCDD once the impact of those developments are determined. While this study does not identify specific relief sewer projects, it does suggest minimum flow reductions needed to alleviate any surcharged conditions in the study area.

3.5 RESULTS

Existing Condition

The peak flow model indicates surcharged sewers:

- The 30" and 60"trunk sewers in Auahi Street and Ward Avenue respectively, on the west side of the KCDD
- A portion of the 21" trunk sewer in Kapi'olani Boulevard near Pensacola Street
- 8" and 24" branch sewers connecting to the 72"Auahi Street between Keawe Street and Cooke Street
- 8" sewer immediately downstream of the Halekauwila Place sewer connection on Keawe Street

New developments with increased sewer demands within the KCDD may not be able to connect to the adjacent sewers because the City does not allow a sewer connection to a line that is surcharged or to a line which discharges to a surcharged line. See Figure 3 in the appendix.

Future Baseline

The surcharged condition under the existing condition is compounded under the Future Baseline scenario west of Ward Avenue. The proposed HHG sewer system improvements will provide sufficient capacity for the HHG developments east of Ward Avenue. The following sewers remain surcharged:

- The 30", 36", 60", and 78" trunk sewers in South Street, Auahi Street, and Ward Avenue on the west side of the KCDD
- The 8", 10", and 12" Halekauwila Street sewers between South Street and just west of Coral Street
- The 10" Pohukaina Street sewer between South Street and Keawe Street
- The 8" sewer immediately downstream of the Halekauwila Place sewer connection on Keawe Street
- The 36" sewer around the former CompUSA building on South and Auahi Streets and Ala Moana Boulevard
- The planned HHG 12" sewer on Pohukaina Street between Koula Street and Ward Avenue and branching 6" sewers on ʻOhe and Koula Streets
- Portions of the 21" trunk sewer in Kapiʻolani Boulevard near Pensacola Street
- The 12" and 18" branching sewers on Kawaihao and Queen Streets, connecting to the 36" sewer in Kamakeʻe Street

See Figure 4 in the appendix.

TOD Alternative A

The surcharged condition under the Future Baseline scenario is compounded under the TOD Alternative A scenario. In addition to the sewers surcharged under the Future Baseline condition, the following sewers are surcharged:

- The 8", 10", and 12" Halekauwila Street sewers from South Street to east of Cooke Street
- The 8" and 10" Pohukaina Street sewers from South Street to Coral Street
- The 6" Ilaniwai Street sewer between Cooke Street and Ward Avenue

See Figure 5 in the appendix.

690 Pohukaina Street Project

The existing sewers adjacent to the 690 Pohukaina Street project have insufficient capacity for the projected wastewater flows and the downstream sewers in South Street and Auahi Street are surcharged. Furthermore, the model indicates the 8" sewer in Keawe Street does not have sufficient capacity for the Halekauwila Place sewage flow.

See Figure 6 in the appendix.

3.6 MITIGATION MEASURES

Future Baseline

- Replace 480 lf of 10" sewer on Pohukaina Street between South and Keawe Streets, SMH 4025647 to SMH 683930, with a 12" sewer.
- Replace 310 lf of 8" sewer on Keawe Street makai of Halekauwila Street, SMH 683930 to SMH 341527, with a 12" sewer.
- Upsize 305 lf of HHG's planned sewer in Pohukaina Street between Ahui Street and Ward Avenue from 12" to 18" diameter, between SMH 379756 and the new 24" sewer in Ward Avenue. Sewer demands from Blocks 48N and 55 (KS D) are redirected to this line as the adjacent 6" and 8" sewers are inadequate.
- City's proposed diversion of sewage flow from the 60" Ward Avenue trunk sewer; a minimum of 27 MGD was used in the analysis.

See Figure 7 in the appendix.

TOD Alternative A

- Replace 480 lf of 10" sewer on Halekauwila Street between South and Keawe Streets, SMH 4025647 to SMH 683930, with a 12" sewer.
- Replace 310 lf of 8" sewer on Keawe Street makai of Halekauwila Street, SMH 683930 to SMH 341527, with a 12" sewer.
- Replace 250 lf of 6" sewer on Ilaniwai between Kamani Street and Ward Avenue, SMH 342208 to SMH 342321, with an 8" sewer.
- Upsize 305 lf of HHG's planned sewer in Pohukaina Street between Ahui Street and Ward Avenue from 12" to 18" diameter, between SMH 379756 and the new 24" sewer in Ward Avenue. Sewer demands from Blocks 48N and 55 (KS D) are redirected to this line as the adjacent 6" and 8" sewers are inadequate.

See Figure 8 in the appendix.

Off-site Diversion

Approximately 132 MGD of sewage flow originates outside the KCDD and passes through the study area. A diversion of a minimum of 27 MGD of sewage flow from the 60" Ward Avenue

trunk sewer will alleviate surcharged conditions in Ward Avenue, Auahi Street, and South Street under the Future Baseline and TOD Alternative A scenarios.

Surcharged Sewers to Remain

With the proposed diversion and sewer system improvements in place, a number of existing branching sewer mains will remain surcharged. Under ideal conditions the top of a branching sewer is typically set at an elevation equal to the top of the trunk sewer to minimize surcharging of the branching sewer. The following branching sewers all connect to a trunk sewer with the branching sewer inverts set at or near the trunk sewer invert. The branch sewer profiles suggest external factors such as a conflicting utility precluded a higher invert connection or larger pipe diameter. In these instances, surcharging of the branching sewers is practically unavoidable.

- The 8" sewer, ID 4065997, at the intersection of Auahi and Coral Streets
- The 24" sewer, ID 3014925, at the intersection of Cooke and Auahi Streets
- The 30" sewer, IDs 685449, 685488, and 3010720, on Auahi Street between South and Keawe Streets
- The 10" sewer, ID 4026585, at the intersection of Halekauwila and Cooke Streets
- The 6" sewer, ID 344232, at the intersection of Archer Lane and South Beretania Street
- The triple barrel 12" sewers, ID 3015527, at the intersection of Kapi'olani Boulevard and Pensacola Street
- The 21" sewer, ID 380522, on Kapi'olani Boulevard, just west of Pensacola Street
- The 8" sewer, ID 4047070, 12" sewer, ID 4046376, and 18" sewer, ID 2023300 connecting to the 36" Kamake'e Street sewer.

See Figure 8 in the appendix.

690 Pohukaina Street Project Sewer Connection

The 690 Pohukaina Street Project is located in the area impacted by the surcharged sewer lines in South and Auahi Streets. In accordance with the Design Standards, a sewer connection to a surcharged line is typically not allowed. The project would not be able to connect to the sewers fronting the property. The following off-site improvement would provide sewer service to the project:

- Replace 480 lf of 10" sewer on Pohukaina Street between South and Keawe Streets, SMH 4025647 to SMH 683930, with a 12" sewer.

See Figure 9 in the appendix.

4 OPINIONS OF PROBABLE COSTS

Opinions of probable costs are estimated for the proposed mitigation measures. A lineal foot unit cost for sewer line installation is derived from recent similar sewer line construction projects. The total cost includes design fees equal to 10% of the probable construction cost and a 25% contingency. The opinions of probable costs are summarized in Table 8 below.

Table 8: Opinion of Probable Construction Costs

Mitigation Measure	Unit Cost	Future Baseline	TOD Alternative A
Replace 480 lf of 10" sewer on Pohukaina Street between South and Keawe Streets, SMH 4025647 to SMH 683930, with a 12" sewer.	$4,125 / lf	$1,980,000	$1,980,000
Upsize 305 lf of HHG's planned sewer in Pohukaina Street between Ahui Street and Ward Avenue from 12" to 18" diameter, between SMH 379756 and the new 24" sewer in Ward Avenue. [1]	$210 / lf	$64,000	$64,000
Replace 310 lf of 8" sewer on Keawe Street makai of Halekauwila Street, SMH 683930 to SMH 341527, with a 12" sewer.	$4,125 / lf	$1,280,000	$1,280,000
Replace 250 lf of 6" sewer on Ilaniwai between Kamani Street and Ward Avenue, SMH 342208 to SMH 342321, with an 8" sewer.	$4,125 / lf	n/a	$1,100,000
Total Opinion of Probable Cost (rounded)		$3,400,000	$4,500,000

1. Fair share cost to upsize the HHG base design.

5 CONCLUSION

The KCDD Mauka Area sewer system is impaired by the larger off-site sewer flows that surcharge the trunk sewers in the district. Sewer system improvements proposed by HHG and herein in addition to an off-site sewer diversion proposed by the City will free sewer capacity within the KCDD.

On-site sewer improvements include:

HHG Proposed Improvements

- Install a 24" relief sewer in Ward Avenue between Ilaniwai and Auahi Streets
- Reroute the 48" trunk sewer from under the Ross Dress for Less and Sports Authority stores into Ward Avenue
- Replace the 6" sewers in Pohukaina Street between Koula and Ward Avenue with 12" sewers
- Install a 36" sewer in Auahi Street between Kamakee Street and Ward Avenue
- Replace the 8" sewer in Auahi Street between Kamakee Street and Queen Lane with a 12" sewer.

Future Baseline

- Replace 480 lf of 10" sewer on Halekauwila Street between South and Keawe Streets with a 12" sewer.
- Replace 310 lf of 8" sewer on Keawe Street makai of Halekauwila Street with a 12" sewer.
- Upsize 305 lf of HHG's planned sewer in Pohukaina Street between Ahui Street and Ward Avenue from 12" to 18" diameter.

TOD Alternative A

- Replace 480 lf of 10" sewer on Halekauwila Street between South and Keawe Streets with a 12" sewer.
- Replace 310 lf of 8" sewer on Keawe Street makai of Halekauwila Street with a 12" sewer.
- Replace 250 lf of 6" sewers on Ilaniwai between Cooke Street and Ward Avenue with 8" sewers.
- Upsize 305 lf of HHG's planned sewer in Pohukaina Street between Ahui Street and Ward Avenue from 12" to 18" diameter.
